Topic: 45058 Message: 45122

I am in Mikes camp and the fellow who said might save 5 hours in 10 years by not cycling the filaments. I doubt any real measurable difference in life expectancy. I think vibration would be more likely to hurt filaments than cycling on off. Reason why the military went to 6146W tubes. Of course not too many folks running mobile hybrids these days.

I have a old RCA tube manual and the tube data sheet for the 6146 describes filament testing. It goes like this.

A quantity of 6146 tubes are pulled from each production run and subjected to following filament testing.

1. With 8 volts applied the tubes are run for 1000 hours continuously

2. With 11 volts applied the tubes are run 1 minute on and 4 minutes off for 48 hours.

At the end of both test periods tubes are tested for filament minimum leakage current and filament maximum leakage resistance criteria (100ua and 10 meg).

I think the 1 min on and 4 min off test sounds like feeding a rat 20 gallons of aspartame (artificial sweetner) a day to see if it gets cancer! I guess it was RCAs version of accelerated wear testing?

There will be lots of anecdotal opinions about whether to run continuous or to cycle filaments on and off. I wonder how often you hear about open filaments versus how often you hear about soft finals?

In commercial broadcasting they use to leave the filaments on all times but they vary the filament voltage.

I should not have mentioned to Ron about final tube emission loss. My real admonishment is why run heaters on the service bench when you are troubleshooting a relay keying issue? If you have a habit of automatically flipping on the line switch and heater switch this is where you will be at on the bench. Unlike many other transmitters and transceivers you do not have to be in that space with a KW hybrid. It is ok if you have rig controls configured so you dont have un-intentional TX that goes unnoticed.

Just the way I do business on my bench with customer rigs and with my KW hybrids.

Terry K9TW

When I owned my TS-820S, I left the HEATER switch set to ON all the time. The TS-520SE I use to own many years ago, did not have a HEATER switch since the 520SE is designed to operate from 120/240VAC ONLY. Kenwood put the HEATER switch in the TS-530 and TS-830. The reference to the HEATER switch in the manual simply states in the manuals that the HEATER switch turns all 3 transmitting tube filaments ON, nothing more.

Heathkit's Apache TX-1 and Heathkit's Marauder HX-10 transmitters both had a separate filament transformers that provided a constant 6.3VAC to the VFO's filaments as long as the main power plug was plugged into the wall outlet. I have both transmitters and ran them for years and never experienced a filament failure or reduced emission due to constant filament power.

Most of my ham gear consist of all vacuum tubes with only 2 all solid state transceivers (Yaesu FT-757GX and FT-857D) and two all solid state receivers (Heathkit SB-303 and a Kenwood R-599D). The tube filaments in the vacuum tube gear are all powered ON the moment the main power switch it turned ON. I have never experienced any problems with power supplies or with filament failure or thermionic emission failure in any vacuum tube used in my gear. I have experienced failures in vacuum tubes but not due to filament issues but rather due to excessive gas collecting in a 6146 because it sat for "20 years" in my HW-101 (the original owner let it sit in his garage for 20 years with no power applied). The failure occurred after 3 days of testing. Surprisingly the 6146As produced full output but after 3 days one 6146A arced when keyed, drive set to minimum. The arcing blew the supply's breaker (HP-23A), no damage to any component in the supply or the HW-101. Replaced both 6146As, problem solved.

Whether you set the KW hybrid's HEATER switch to ON or OFF is entirely up to you. I doubt you will experience filament failure due to stressing the filament by powering the filaments ON and OFF each time you power up your KW hybrid or if you leave the HEATER switch set to ON while you are using your hybrid.

Mike, I have been leaving my heating filaments on per the admonition of several old timers in order too avoid thermal stress that can cause the heater to fail before emisivity falls off. I tried to start a thread along these lines, but I don't recall you weighing in.

Just curious as to your pro/con reasoning here.

Chris KQ6UP

On Oct 6, 2013 4:52 AM, <wagstw46@...> wrote:

I think you are Red and perhaps now Black and Blue!

Your rig and you can chose to run with heaters on at all times if you want. Folks do but I would not. Lots of rigs with no heater switch. KW provided it to facilitate mobile operation to lessen drain on battery.

How did you see the plates glowing red? Were you looking inside PA cage for source of relay keying issue?

Was the radio working in receive mode during this 10 minute period before they turned red?

If no receive are you sure the relays are not keyed and rig is in standing TX mode?

If good receive then relays not keyed and about only way for finals to take! off in receive mode is a problem with cut off bias.

Terry

When I said "Sorry Mike" I was apologizing to Mike for butting in on his thread.

I was not Chastising Mike in any way. His advice to try keying the rig by grounding mic jack Pin 2 was spot on. If Send switch and mic PTT wont key rig Mikes direction is the next logical step.

I was trying to very quickly get Rons attention to get the damn Heater switch turned off. Why would anyone troubleshooting a rig keying problem have the heater switch on?

And sure didnt want Ron to re-fuse the rig and try burning up the Plate choke or the HV rectifier board, or the Power transformer.

I am sorry and should have let it go. No way for me to know if Mike or anyone else was monitoring and could stop Ron from further damaging his rig. Felt like could not just sit on sideline and watch him do this.

I apologize to Mike if it looked like to one or more of our members that I was chastising Mike. We can all have professional differences but none exist related to this thread.

I am sorry Mike:

TURN THE HEATER SWITCH OFF MAN!

Why would you have the filaments on when troubleshooting a relay keying problem? There is no reason to have the heaters on until a few minutes before ready to load and transmit. Tubes only have so much life and running heaters all the time is not necessary.

If heaters are off then can be no cathode emission and if you lose cut-off or operating bias there will be no Plate current.

Likely you have lost the final tubes. They do not like thermal run away. How did you see the plate glow? Do you have the PA cage cover off? If so why? Have to be very careful with 900vdc present here.

Will let Mike help you trouble shoot this problem as well as the relay keying issues. Not likely related.

Just do not put heaters back on while working on the relay keying problem.

Hi Ron,

Have you tried grounding pin 2 on the MIC socket to see if the relays energize? Pin 2 on the MIC socket is in parallel with the SEND switch.

The meter switch settings are not enabled in receive. The 820 has to switch to transmit (relay on the RELAY Unit) must energize for the meter switch settings to work.

I agree if the repairs required very stable oscillators, more sophisticated o'scopes, digital test gear, and sensitive volt meters which is typical of the more advanced modern day ham gear. However, for most vintage ham gear problems, troubleshooting and repairs can be accomplished using simple basic test equipment. I've repaired Kenwood, Collins, Heathkit, Drake, Knightkit, and Allied vintage ham gear using nothing more than the test equipment shown in my video.

45124. Kenwood Net Update 10/6/13

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-06 20:49:58 UTC
From: Mark Gilger
Topic: 45124 Message: 45124

The Saturday□s net on 40 meter had 25 stations
checking in under Excellent band
conditions. There were 8 new check-ins, W1RF,
WA2RVJ, W3TLB, WB2PAY, KD8GYS, N2RRR, KZ3AB,WX1MAN. Out of those, there was:

```
3 running TS-520(x)
1 running TS-530(x)
4 running TS-820(x)
3 running TS-830S
2 running 599 Twins

Jimmy, WB2KNR ran the net today with his TS-520.
The rest were running non hybrids of one model or another.
```

The Sunday□s 20 meter net had 13 stations
checking in under poor band conditions. Out of those, there was:

```
3 running TS-520(x)
0 running TS-530(x)
3 running TS-820(x)
2 running TS-830S

I was running my TS-940. Seems everyone today was
running a solid state radio of one type or another.
```

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

```
If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.
```

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins

November 2012, Saturday☐s, net total = 47, Sundays total = 20
December 2012, Saturday☐s, net total = 74, Sunday☐s total = 70
January 2013, Saturday☐s, net total = 93, Sunday☐s total = 87
February 2013, Saturday☐s net total = 103, Sundays total = 87
March 2013, Saturday☐s, net total = 112, Sunday☐s total =39
April 2013, Saturday☐s net total = 52, Sunday☐s total = 29
May 2013, Saturday☐s net total = 45, Sunday☐s total = 50
June 2013, Saturday☐s net total = 30, Sunday☐s total = 27
July 2013, Saturday☐s net total = 63, Sunday☐s total = 41
August 2013, Saturday☐s net total = 82, Sunday☐s total = 50
September 2013, Saturday☐s net total = 66, Sunday☐s total = 54
October 2013, Saturday☐s net total = 25, Sunday☐s total = 10 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

The Heater switch was "backwards"?? Do you mean it was "Mounted"
backwards or what?

You got the relays to key now? What did you do to get the relays to
energize?

The bias is unstable? How did you determine the bias is unstable? Is the
60ma idling current fluctuation/unstable in USB or LSB transmit or what?

Mike W5RKL

Mike and Bob, being an "Old Timer", I can understand your frustration. Back in our day, we grew up on vacuum tube equipment. First, we might have replaced tubes in our parents B/W TV sets, by taking every one of them down to the corner drugstore, testing them in the "match the number of the socket" tube testers, and then using the tube placement chart inside the cabinet of the TV to (hopefully !) get every tube back in the right place inside that TV.

If we passed that test, and the TV worked again, we might graduate to one of those simple kits manufactured by most notably Heathkit, Knight-Kit, or one of the other rather numerous kits at the time. Tube testers, VTVMs and VOMs, simple SW/Ham radios, etc. were all fodder for our young minds to grow on.

Today's "newbies" don't generally have that background to draw on when they jump headlong into amateur radio. Also consider that they (and we) are living in an "instant gradification" world. If they choose to operate a Vacuum Tube Hybrid, they are going to want it to work RIGHT NOW and might even be impatient because it takes 10 or 15 seconds or longer for the tubes to come to life !

The Heater switch was "backwards"?? Do you mean it was "Mounted" backwards or what?

You got the relays to key now? What did you do to get the relays
to energize?

The bias is unstable? How did you determine the bias is unstable?
Is the 60ma idling current fluctuation/unstable in USB or LSB
transmit or what?

Mike W5RKL

Newbies might ask the questions because the want adivise from those more experienced in the radio they are asking about. How will they every learn if no once will advise them. They might be new at these types of radios. I do not think you need to be an experienced tech to enjoy them. Some may ask the questions so they do not have to waste time trying to figure out the problem. It might be a simple solution to the problem.
You do not need test equipment to be in the radio hobby.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

I have made these same observations. If newbies don't want to follow the instructions they should not be messing with these radios.

If you don't want buy the necessary test equipment this is not a hobby for you!

Subject: Re: [TS-520_820_530_830] Following instructions

Yes, I could have included a statement that said, "follow instructions that are backed up with actual facts and explanations why you should perform the instructions". I did not include that statement or something similar because more often than not, instructions provided to member on this group, more often that not, include facts and supporting statements why the instructions should be followed. Yes, I know there are some suggestions that are pure non-sense and out right wrong but when those appear, the factual statement/instructions point those out and why they should not be followed.

Something I have a difficult time understanding is a ham who has no basic knowledge of electronics, can't read a schematic, has never performed any troubleshooting, and doesn't have nor has ever used test equipment, believes they can repair their sophisticated KW hybrid by asking a few questions. While they may be "trolling" for answers so they can the answers to someone else who is experienced, I suspect most of the time that is not the case. There has been many times where I have seen members say, "I don't have the experienced/knowledge but I want to learn". That's a great idea but unless that member(s) actually spend time reading and studying and asking questions about topics they are having troubles understanding, the statement is nothing more than words on a computer screen. Learning electronics not something you learn overnight, over a weekend, or even within 6 moths. It takes time to study and that means reading reference material that has been

provided many times on this group. I don't know how one is going to learn if they are not interested in reading/studying? Maybe because, as many thing are today, "There's not an ap for that!!".

I'm no expert, I have never said I was. However, I didn't learn what I know by sitting on my butt and having someone else do the work. I still read/study/review the basic subjects such as resistors, capacitors, inductors, power supplies, receivers, transmitters, and other electronic subjects. Again, a person will not learn it overnight, over a weekend, or even after 6 months. It takes time to study and ask questions.

Again, I mean no disrespect towards anyone.

I would be very interested to know if you have an SWR (standing wave ratio) bridge between your Kenwood
and the tuner. In my experience you can get some pretty weird mismatches with an arrangement like yours.
For example your 80 metre dipole would be reasonably OK on any band where you have an even harmonic relationship
like 80/40/20. On the WARC bands all hell could break loose in your Kenwood or your antenna tuner.
BUT without a Balun or a choke wound in your Coax you will very likely get a lot of RF on the outer
shielding which can cause problems.
You have to realise that wire antennas (unless tuned against ground) are basically a balanced system and coax cable
is Un balanced, by definition.
In my youth I remember a few RF burns caused by very high SWR and mismatches even when I was running only 50 watts or so.
We all had to learn at some time after all.

In essence that is why I am a big fan of balanced lines. They are-
1. Easy to make.
2. Cheap to make with everyday materials.
3. Have lower losses at HF frequencies.
4. Don't use those @$%$@#$% "UHF" connectors (which I hate with a passion). So many problems are caused by faulty connections
with the shielding or melted coax insulation!!!
5. Handle moderate mismatch without major losses.

Don't get me wrong my 5/8 wave 20 M vertical is fed with 50 Ohm coax but the G5RV is fed with glass sheathed brass studding drilled through the 20 cm thick concrete blocks of my basement with cone insulators at each end. The glass protection was cut from laboratory glass tubing to fit.
The balanced feeders go all the way to my Z match tuner.
It took a bit of trouble to do with a long masonary drill but it was well worth it.

Hi MIke!
Just last week I got a request that shows how Ham Radio is not the only hobby that suffers from, what I
often call the "instant gratification syndrome".
The secretary of a local government committee that I am on asked me to look at a modern "GO TO" telescope
that her husband had but didn't know how to use. You might have seen them, they have a lot of electronics in them that
automatically point the scope at an object on their data base, or at a given position in the sky.
BUT, of course they have to be set up for their location and direction.
Unfortunately this guy had NO knowledge of Astronomy at all. In fact if he read a book written for kids of 10
he would know quite enough to operate it. But apparently he didn't have enough interest to do that, so a $1500
scope sits idle.

My own scopes aren't as busy as they once were but then I am getting some eyesight problems.

So you see Ham radio isn't alone. BTW isn't there a technical exam still in North America for your Ham licence?
If it was even half as difficult as the NZ one still is, I can't understand how someone could be licenced without
having at least a basic knowledge. Perhaps it is all those multiple choice questions and crib sheets?

My solution is what my grandsons call my "Igor" switches. The line comes into some big
old fashioned DPDT knife switches with built in discharge points.
That means that my feeders are disconnected from the rig when lightning is around and the
build up of static is limited. There is a good earthing system to 4 copper pipes buried about 2.3 Metres
into wet soil and the antenna can be grounded, or switched over to a 400 Ohm bulb dummy load.

"Igor switches" are like those used by the assistant to Baron Frankenstein for monster animation!!!

But these aren't quite as big as the movie version just abut 80mm by 40 on the ceramic bases.
Works OK here, but we only get lightning very occasionally NW of Auckland.

Joe,

The Lego tuning tool works very well. I got 10 MHZ to pop up to an S5 adjusting the rear, then i went to the front coil and it wasnt doing anything. I re re checked to make sure I was on the right coil. but it just stayed at the bottom of the can. I went back to the first coil and without much effort, the slug slipped to the bottom. So now I have two slugs sitting on te bottom of the cans. Is there a way to push them back up? I was concering de solderin them to see if it was open on the bottom, then push them back up to the top. and then resoldering.

any experience with these?

steve

Steve,

I have the 5 pc version...but I did get a real good deal on an NOS tv alignment set...this had everything I could possibly need,
especially some long shafted tools to get to some on the tuning coils...ie..T-4 on the 830 RF board...as this tool is flexible.
It was actually rather cheap...$30.00.

Gordon's method sounds fine...about heating the tool...I have not used that method...but I trust his judgement,,,he's been at
this a lot longer than I have..hihi. I have several different coil slugs that are found on/in the KW hybrids...I use them to "fine tune"
my exacto knife approach as the slugs are junk(broken in half)...and I can observe them

under my magnified light..remember...
use "decaf" coffee...those damn blades are sharp!

I am shooting from the hip here...as I don't have a schematic in front of me...but with all else being equal...there maybe
some "crud" on the associated band switch contact points...as the "cal signal" I believe is inserted after L-41..(antenna step xfmr)
so should eliminate that as a possible problem. What is the difference between the "S" meter readings? They will tend to decrease
as the band changes go higher in frequency...but should NOT fall off from say, "S-9" on 20M to "S-3" on 10M

I do not want to steer you in the wrong direction...others here have WAY more diagnostic skills than I do...so, I shall reserve
my recommendation to what my limited knowledge allows me to do

Steve,

Were you trying to turn them and they just went to the bottom?

It is NOT uncommon for this to happen. I've had it happen to me about 4-5 times on 530/830's

There are several methods: one is to use a very small amount of "super glue" on the very tip on the tuning tool,
  making sure the the tip goes into the slot...and the tool/tip remains vertical. You get glue between the slug and
the thin plastic insulation...you are in trouble!! Don rush..let the glue set up for a few minutes...then SLOWLY & CAREFULLY
rotate (counter-clockwise as seen from the front) the tool while applying slight up force...see if it comes up. Take your time...you may have to try the glue several times.

  The second is to unsolder the offending can and you can insert your tuning tool in through the bottom and turn & push up to the
  the slug up and out. Take notes on the orientation...most will go back in only one way...but why push your luck.

 I like the second method better...super glue in a coil form scares the @*#$ outta me.

  Once the offending slug(s) are out you can use a small piece of waxed dental floss between the slug and the inside of the can
to take up some slack, and the wax on the floss acts as a lubricant.

  Do not use any metal tool or tools on or around those tuning cores/slugs...they will get really mad and break...compounding your problem.
  They also have slots on both ends...so they can be swapped end for end.

 These are the two most common methods...good luck & GO SLOW

I was thinking of a similar method, only I was considering super gluing a wood dowel on..again I had reservations about using too much glue etc. if it worked to get it up, i would simply leave the dowels attached for the next alignment. I think I will investigate your second method first though. Is the slug threaded? maybe some wax on the threads would take up the slack..but it could also give way if it got to warm.
BTW where is T2. I see TP2 next to a can..but i am thinking that might be a TEST POINT that I also dont see.

I havent found a printable manual yet, so i have the PDF on the iPad..is there one here in forum..I havent found it yet...or on the web.

thanks.

Joe,

The Lego tuning tool works very well. I got 10 MHZ to pop up to an S5 adjusting the rear, then i went to the front coil and it wasnt doing anything. I re re checked to make sure I was on the right coil. but it just stayed at the bottom of the can. I went back to the first coil and without much effort, the slug slipped to the bottom. So now I have two slugs sitting on te bottom of the cans. Is there a way to push them back up? I was concering de solderin them to see if it was open on the bottom, then push them back up to the top. and then resoldering.

any experience with these?

steve

No Joe, I dont get a good cal sig on 30. most other bands are close to or at S9, Thats what makes me wonder if its not "something else"

There are two tool sets on amazon..one have 5 pc the other 12 (I think) which one did you get?

thanks

Steve,

I have used the "alignment tool set" from "Amazon" that your were talking about in your original post. The thing that you
will have to do is take a very sharp knife...say an exacto...and trim back some of the plastic as the end is at times too short
to get to the slug, as the shoulder of the tool can hit on the top of the "can." Or, go to a hobby or craft store and look for a piece
of plastic rod that you can "custom" make your own...or a nice piece of dowel stock.

I do not know enough about the noise blanker circuit to offer a logical/correct answer. I think that Terry-k9tw, just answered
something about a noise blanker a few posts ago.

As far as 30m goes...check for proper adjustment of the associated coils first. Can you get a good "cal signal?"

Hi guys,,,I dont know where my post went, maybe into the land of rare DX . Strange thing is I saw a reply last night, where someone suggested K4EAAs site..oh well....but I was wondering if anybody has seen where to get alignment tools for the 530s. Ken sells them for the 520, but not the 530.
Also the noise blanker isnt working. Any ideas.

Also 30 meters is very low on recieve, all other bands okay. anything there besides an alignment?

I didnt really push that hard, if you'd call it a push at all. I think the weight of the tool took it to the bottom, the other one was already bottomed out. do you have a suggestion to regain the threads?

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

They should NOT be pushed, they should be turned (screwed). If the "pushed to the bottom, you have lost the internal threads.

My last post got sent before I was really finished with it. But I read it through, and it is probably about as complete as I wished it to be, anyway.

I am the Editor of our Astronomy Club's newsletter "The Observer". I have placed as high as 2nd place in the country with the Astronomical League for excellence in newsletter publications, and have held an Amateur Radio Extra since the late 1960s, so I believe I can remark with some authority on the subject of "goto" telescopes, reading the manuals, and finding such technical devices as telescopes and radios ending up in closets.

Unfortunately, along with the simplifying of the examination system in the U.S., a simplifying of the expectations of operating an amateur radio has also come about. Some people call it a "dumbing down" of the hobby. Just like the "goto" telescopes have generated a expectation that ANYONE can take a telescope, plop it down on the ground, push a few buttons, and see such far away and dim sights as the Great Andromeda Galaxy, the Double Cluster of Persues, or the Orion Nebula, Ham Radio has generated the expectations that anyone can purchase a radio, and a G5RV antenna, string it (the antenna that is) up between two clothesline poles and "Work the World with Amateur Radio" . And when a person attempting to do either hobby fails in their expectations, they throw the equipment into the closet and go on to another hopefully less technically oriented hobby. It is a doggone shame that this has happened in two wonderful hobbies. Model Aircraft is another hobby that is victim to the "gotta have it now" syndrome. Hardly anyone builds model aircraft from balsa and plans, any more.

I see that you are having eyesight problems. Have you considered taking up astro-photography? You want to talk about technical challenges. We could, but that would be totally hijacking this thread.

You can reach me at jimstan@... if you would like to know more about astronomy and astro-photography!

The American Amateur Radio exams are tough? Heck no! The Amateur Radio exams have become much easier and the FCC has relaxed the requirements to become an Extra Class ham. Years before an applicant had to be a licensed General or Advanced class for a minimum of 2 years before they could apply for and take the Extra exam. Now anyone who thinks they can pass it can take it even if they have never held an Amateur Radio license before!

I think you have it over simplified. On the old test it was the advanced that was the hard test now it is split up between the general and extra class tests so you don't get bombarded on one test plus the theory has changed just like the technology (plug and play) besides how many hams will build a antenna let alone a radio. I think we have spoiled people by not doing the heavy theory. The hard part is getting people to remember the theory instead of just learning enough to pass the test. Thanks to Gordon West to make easier learn enough to pass the test. Hams are different from when I started compared to now. Granted it made it easier for the 11 meter crowd to become hams and making it appealing to them in my area we have a decrease in 11 meter interference . I guess as a VE I have to accept the lesser of the two evils and so be it at least we are getting more usage on the bands . But what we need is for hams to stay hams instead of falling to the wayside.

I was simply saying that it's much easier today to get a ham license
then it was back in the 60s and 70s.

Just make sure that you get ALL the band switch wafers properly aligned! Take some pictures...or draw diagram..getting
them out of "sync" without knowing it WILL drive you nuts...

I got some alignment items off "amazon"...... search for radio/tv alignment tools.

The larger set, I got off ebay....it has stuff I will probably not use...but it did have what I needed.
I found no "part numbers" on the items. You may also browse "digikey" or "mouser" electronics. You really can make all the tuning tools/wands easily. I just
got lazy.

I live in a city of 200K people...the last decent electronic supply house closed up 2 years ago.
Seattle is about a 30-40 minute drive...then try and find a place to park

IF, the tuning slug is very deep in one/both of the 10Mhz cans as stated...that may be the reason for your low "cal" signal.

Take your time... and document your work! Keep a notebook with some pics and your notes...they could come in handy
sometime down the road.

I have the rig apart, now. I am waiting on Kens couples before i power up again. The plastic coupler on the band switch is broke. i was able to tighten up a bit as the screws were loose as well. Then when i was going through it again, i noticed that one of the set screws was now hanging out...by a thread. (haha) so i pulled that screw out, others are loose because the plastic scratched. i dont want to risk having a screw fall out when 900 volts is on. so once that is fixed, i will clean the contacts again (also will swap out the resistors on the final board and change the driver) THEN I will start recking the alignment again . All looked pretty good with the cal signal all close to S9...except 10 MHZ , like I said was really low S2 or 3 i think.
I found a little plastic rod in my sons lego stuff. It fits down into the can nice. Its short, so I glued into a tube used from a can of compressed air. I will carve and file tomorrow and try for fit. where did you find the NOS tools at? Amazon, Ebay? does it have a name or part number?

Thanks porcupine

No Joe, I dont get a good cal sig on 30. most other bands are close to or at S9, Thats what makes me wonder if its not "something else"

There are two tool sets on amazon..one have 5 pc the other 12 (I think) which one did you get?

thanks

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Steve,

I have used the "alignment tool set" from "Amazon" that your were talking about in your original post. The thing that you
will have to do is take a very sharp knife...say an exacto...and trim back some of the plastic as the end is at times too short
to get to the slug, as the shoulder of the tool can hit on the top of the "can." Or, go to a
hobby or craft store and look for a piece
of plastic rod that you can "custom" make your own...or a nice piece of dowel stock.

I do not know enough about the noise blanker circuit to offer a logical/correct answer. I think that Terry-k9tw, just answered
something about a noise blanker a few posts ago.

As far as 30m goes...check for proper adjustment of the associated coils first. Can you get a good "cal signal?"

Hi guys,,,I dont know where my post went, maybe into the land of rare DX . Strange thing is I saw a reply last night, where someone suggested K4EAAs site..oh well....but I was wondering if anybody has seen where to get alignment tools for the 530s. Ken sells them for the 520, but not the 530.
Also the noise blanker isnt working. Any ideas.

Also 30 meters is very low on recieve, all other bands okay. anything there besides an alignment?

steve

AS to Amateur Radio exams. In NZ we used to have a "novice" system for 2 years on 80 m and vhf.
I think that's long gone and we now still have technician class (VHF/UHF) and General.
Our exam was reasonably tough a year or two ago, but I think that the "tick the box" syndrome has
been a bit of a killer. Still I have yet to meet a local Ham who was ignorant of Ohm's law or Voltage,
Power and current measurement (long may it continue).
I was never rich and always made as much of my gear as I could. Even now the Kenwood TS820s
is my (much modified) only bit of commercial gear apart from an Advance sig gen and a new 150 MHZ
digital scope. I built my telescopes too, except for the optics.

What puzzles me is how folks these days will spend days learning how to drive some new flash computer
or tablet App but don't have the time to study up on simple skills.

Thanks for the suggestion about digital astro photography I'll contact you some time on that.

the glue trick worked!!
are you north or south of seattle?

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Just make sure that you get ALL the band switch wafers properly aligned! Take some pictures...or draw diagram..getting
them out of "sync" without knowing it WILL drive you nuts...

I got some alignment items off "amazon"..... search for radio/tv alignment tools.

The larger set, I got off ebay....it has stuff I will probably not use...but it did have what I needed.
I found no "part numbers" on the items. You may also browse "digikey" or "mouser" electronics. You really can make all the tuning tools/wands easily. I just
got lazy.

I live in a city of 200K people...the last decent electronic supply house closed up 2 years ago.
Seattle is about a 30-40 minute drive...then try and find a place to park

IF, the tuning slug is very deep in one/both of the 10Mhz cans as stated...that may be the reason for your low "cal" signal.

Take your time... and document your work! Keep a notebook with some pics and your notes...they could come in handy
sometime down the road.

☐
The only positive solution for lightning protection is to disconnect the
feed line from the shack where it enters the building. And move the feedline
as far from the building as possible.

I spent 4 years doing lightning protection on telescopes on top of
mountains in Arizona. Look at the photos of lightning at Kitt Peak (KPNO).

There are areas of the US that are lightning prone. And lightning is
completely unpredictable.

Don't say that disconnection the feedline is too inconvenient. It's the
cheapest and most positive solution.

Spark gap.

Make some pointy copper/brass spikes (should look like a copper nail)m or you can use some copper-clad carbon arc light or welding rod. One goes on the ladder line wire, the other gets tied to a solid ground with about an eighth of an inch between the points. Of course you need one pair for each leg of the ladder.

Or you can use some non-resistor spark plugs (check tractor supply places if your local auto parts store doesn't have any non-resistor types, or maybe chainsaw/lawnmower repair shops), one per leg, leading to ground on one side of the gap.

Either way, the idea is to give the bolt an easier path to ground than the one presented by your radio and its ground.

Glue trick worked!

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Steve,

Were you trying to turn them and they just went to the bottom?

It is NOT uncommon for this to happen. I've had it happen to me about 4-5 times on 530/830's

There are several methods: one is to use a very small amount of "super glue" on the very tip on the tuning tool,
making sure the the tip goes into the slot...and the tool/tip remains vertical. You get glue between the slug and
the thin plastic insulation...you are in trouble!! Don rush..let the glue set up for a few minutes...then SLOWLY & CAREFULLY
rotate (counter-clockwise as seen from the front) the tool while applying slight up force...see if it comes up. Take your time...you may have to try the glue several times.

The second is to unsolder the offending can and you can insert your tuning tool in through the bottom and turn & push up to the
the slug up and out. Take notes on the orientation...most will go back in only one way...but why push your luck.

I like the second method better...super glue in a coil form scares the @*#$ outta me.

Once the offending slug(s) are out you can use a small piece of waxed dental floss between the slug and the inside of the can
to take up some slack, and the wax on the floss acts as a lubricant.

Do not use any metal tool or tools on or around those tuning cores/slugs...they will get really mad and break...compounding your problem.
They also have slots on both ends...so they can be swapped end for end.

These are the two most common methods...good luck & GO SLOW

Joe,

The Lego tuning tool works very well. I got 10 MHZ to pop up to an S5 adjusting the rear, then i went to the front coil and it wasnt doing anything. I re re checked to make sure I was on the right coil. but it just stayed at the bottom of the can. I went back to the first coil and without much effort, the slug slipped to the bottom. So now I have two slugs sitting on te bottom of the cans. Is there a way to push them back up? I was concering de solderin them to see if it was open on the bottom, then push them back up to the top. and then resoldering.

any experience with these?

steve

45146. Alignment and coil adjustment tools

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-07 06:35:53 UTC
From: Wes Will
Topic: 45055 Message: 45146

I keep seeing people making coil-slug tuning tools, and asking where to get the proper tools.

Maybe we could list some of the sources for these kinds of things in one place somewhere, so people searching earlier posts can find them?

For instance, have you all heard about

minute-man.com?

Cheap tool source, has a fairly big selection. Their only real drawback is a twenty-dollar minimum order, but even I can come up with a double-sawbuck. Look into their item 63-8420 ($4.89) or 63-8454 ($5.52) or 63-910 ($5.86) if a set of tuning tools is what you're after. The page at

http://www.minute-man.com/acatalog/TV_and_Radio_Alignment_Tools.html

shows all of those items, single tools for a couple of dollars if you spot the exact item you need, and some dental-probe kind of soldering aids for six or eight bucks a set.

They also carry resistors, semi-conductors, and wiring products (terminal strips, connectors, and the like). Their basic catalogue listing is rather clunky, but it is here:

http://www.minute-man.com/acatalog/

If there are three or four people in close physical proximity (local club members for instance) you could order three or four sets to get that minimum order size and split the shipping to save a little cash.

I hate seeing people having to fiddle about for lack of the right tools to do the job. These are not the absolute finest quality tools you've ever seen, but we are talking all-plastic hex-end slug chasers here, they don't need to be titanium and sapphire.

For the $20 minimum order, plus something for shipping of course but they've never done me too badly there, you can get a couple of sets of tools, some stainless steel solder picks, and a plastic inspection mirror - great for looking into some of the more inaccessible crevices in one of our pet radios to check for cracked traces or burned solder pads or the like.

It is not the 'prettiest' web site I've ever seen, clunky like I said above, but it is simple and it works well enough for my purposes so far. I have never had any problems with them for quality or shipping, though that's only been tested across three orders total. As always buyer

beware on the internet.

From: fpath fpath
Topic: 45103 Message: 45147

Hi Guys,

I have sat here reading all these posts and there are valuable comments. However, if a person has no idea on how to operate these radios the very best thing to do is read the manual as Mike, Terry and others suggest. Then ask questions for clarification, no issue. But when people who have no idea ask questions and then disagree or fail to follow great advice or instructional advice, one would have to ask how in the hell did they get a licence or survive in the workplace

As an example, I have repaired a 520s, 5 times for the same issue, all because the so called licenced ham believes he knows best, yet continues to take advice from a CB wanker after being shown numerous times how to tune his 520 properly, I no longer help this individual, he is paying $150 per hour for labour at a professional workshop. My time is valuable to me and as I don't charge hams for labour it gets a bit tiring. If a person who wants to learn and follows the advice of the SME (specific material expert) and then continues to ask questions, applies and learn, no one from this group scolds or flames the individual, even if they ask for further clarification - no such thing as a stupid question when your learning, only a stupid person who doesn't ask a question and stuff things up.

Mike is doing an outstanding job on making videos and explaining things. It would be fantastic if Terry, made some videos on how to do a basic alignment, neutralize tubes, how to measure voltages etc, but he does so much now it would be unfair to expect any more. Terry, Mike and others put in a huge amount of time and effort with little or no thanks, for which I will be forever thankful!

I have had some weird issues and Terry, has worked with me off list for weeks on end, going through the issue time and time again and getting the right voltages yet not being able to get to the source of the problem. Sometimes it's just a matter of stop working on it, leave it for a few days and clear your head and start from the beginning.

I'm off my soapbox now. Thanks to all who support this group and attempt to help others and getting back to the way ham radio use to be, experimenting, learning and helping one another.

73's

Dave

Subject: Re: [TS-520_820_530_830] Following instructions

I would agree with this mostly. However I don't advise someone to blindly follow advise that doesn't make sense to them. Make sure you understand the reasoning behind the expert's

advise. If it does not make sense to you, you should have the elmer explain there reasoning. Elmer's should also be patient with this process. It is a part of the learning process -- the most important one. I have had elmer's loose their cool more than once.

This also clears miscommunication, and prevents one from being led down a rabbit hole. Terry did a great job in this respect -- Kudos :D
My $.02,

Joe what's your approach for "unsoldering the can"? If we're talking about the coils on the RF board, then it's always puzzled me how they can be desoldered, as the shafts for PA tuning go through the boards, so looks like major dismantling job to get them out the rig for desoldering. What are other folks doing faced with this? 73s Adrian G4IQW

45150. Addendum to one of the files in the file list - 830 diodes pdf.

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-07 10:52:24 UTC
From: Wes Will
Topic: 45103 Message: 45150

One of the files in the archive, the one concerning the factory-recommended mods to the TS-830, has a notation that there is data missing for the MV-203 diode which is recommended for a replacement of some stock parts.

I don't know if anyone has followed up on that note, can't seem to find any reference to it. The MV-203 is a 'stabilizing diode' used to keep bias and other voltages (usually inputs to a transistor oscillator or amplifier stage) within tolerance. An equivalent to it is:

ZTE-2
BZ102/2V1
BZX75C/2V1

Either one is listed as a cross-reference compatible with the MV-203. Basic specifications are:

Uz 2.1V
Iz 80mA
Rz 19.5Ω
N 0.25W

So basically a 2.1v quarter-watt Zener.

An MA27T-A would also be an acceptable replacement, but it's another obsolete diode type. Roughly 2V, 2,04 or something like it, plenty close for this kind of application.

Don't know if the cross-references to other obsolete parts will help in finding one, but the specifications ought to.

There seems to be some of the BZX75C/2V1 in stock in the UK, only 40 pence a pop, but the shipping could kill you, price-wise:

http://www.signalsuk.com/signalsuk.nsf/ViewSC?OpenForm&cat=Diode+Zener

Look down the list, they have the part number in there, but without the slash - BZX75C2V1 . I know nothing of this dealer whatsoever. Minimum orders and shipping to the U.S. or other countries has to be taken up with them. It could be that a UK ham could re-mail something if they were of a mind, and perhaps compensated for their troubles and the risk of the forty p and postage, but that's nothing I can even guess at.

Would this information be of any use in updating that pdf file? Or in helping 830 owners get diodes for these mods?

>> I think you have it over simplified. On the old test it was the advanced that was the hard test now it is split up between the general and extra class tests so you don't get bombarded on one test plus the theory has changed just like the technology (plug and play) besides how many hams will build a antenna let alone a radio. I think we have spoiled people by not doing the heavy theory. The hard part is getting people to remember the theory instead of just learning enough to pass the test. Thanks to Gordon West to make easier learn enough to pass the test. Hams are different from when I started compared to now. Granted it made it easier for the 11 meter crowd to become hams and making it appealing to them in my area we have a decrease in 11 meter interference . I guess as a VE I have to accept the lesser of the two evils and so be it at least we are getting more usage on the bands . But what we need is for hams to stay hams instead of falling to the wayside.

Not to mention the CW requirement has gone away completely! Personally, I think the FCC should have retained some sort of CW requirement for the Extra privilege!

(No. I am not an Extra, but I passed my novice in 1962, with a code speed of 26 wpm. I *think* could still do 25 characters per minute, [5 wpm] if I had to...wouldn't say much about my fist though...more than likely, very laughable!)

I bet if you looked at the licence issue dates, you'd see a huge bump in the early-to-mid-80s as people got bored with CB and moved onto bigger and louder toys.

Certainly my late father Ralph GM0EXW got both his B and A licence at roughly the same time as a group of people he knew from his interest in the (old, illegal AM) CB scene. 27MHz wasn't doing it, so it was time to get a licence and use 7MHz instead. That's round about when my interest in the hobby started too, but my mum made it quite clear that I'd be far better off studying for school instead of any amateur radio licence, particularly if I wanted to eat my dinner in the house ;-)

I do sometimes wonder if I'd get quite so much of the "Oh you've got an M callsign so you must have just heard about radio last week, you stupid kid" attitude from people old enough to know better if I re-activate my dad's old GM0 callsign.

Topic: 45103 Message: 45159

Perhaps, following the FCC commercial license model, the Amateur Extra Class could be divided into two licenses. One would be the Amateur Extra Class Radiotelephone license and the other the Amateur Extra Class Radiotelegraph license. The former would grant all privileges EXCEPT operation in those exclusive 25 KHz CW segments now set aside for Extras. The Radiotelegraph license, requiring passage of a 20-wpm code test, would authorize its holder to operate on all U.S. amateur band frequencies. The written tests would be identical and Radiotelegraph endorsement issued to current Extras upon the successful completion of the code test.

Creation of an Amateur Extra Class Radiotelegraph license would help smooth the ruffled feathers of the rugged, he-man "vintage" Extras who bemoan the fact that "anyone" can get the top class license these days. Hey! I'd go for it.

By the way, the older Extras may have a point. I just upgraded to Extra yesterday with a perfect, 100% test score. If THAT's not proof that the new tests are too easy, I don't know what is. :-)

The MV-203 is a varactor diode, not a zener. Any stabilization that it would do would be in a voltage controlled frequency control loop, not in a voltage stabilizing circuit. The original MV-xxx numbers stood for Motorola Varactor.

Ct{Cj} Nom. (F) Junction Cap. : 11p

C1/C2 Min. Capacitance Ratio : 4.3

V(RRM)(V) Rep.Pk.Rev. Voltage : 30

Q Factor Min. : 300

f(co) Min. (Hz) Cut-off freq. :

P(D) Max. (W) : 250m

Semiconductor Material : Silicon

Package Style : DO-35

Read more:
<http://www.americanmicrosemi.com/information/spec/?ss_pn=MV203#ixzz2h3gtwiEi>
http://www.americanmicrosemi.com/information/spec/?ss_pn=MV203#ixzz2h3gtwiEi

IF there are small zeners that need some replacements that are hard to find, I recommend a replacement with TLVH431 3 terminal shunt regulators. These versatile devices with a couple of resistors work extremely well to make ideal zeners and they are adjustable with the right resistors from 1.24V up to about 37V. They are available in TO-92 packages making them simple to solder and TI can sample them if you go on their website. I have no affiliation with TI-they were a competitor of mine at one time. NXP has the same devices but not in TO-92. They are not very high current shunt regulators, but with a few more parts even that can be fixed.

From: Gordon JC Pearce
Topic: 45162 Message: 45162

When I tune up on any band following the instructions in the manual (which are how I've been tuning up valve PAs for quite a long time now) I notice that the LOAD control is fully anticlockwise (VC2 fully meshed) when I tune for maximum deflection on the RF meter.

I'd expect this to be somewhere around the middle (ie. with the plates half-meshed). It doesn't seem to make a difference which band I'm on, although on 20m maximum deflection is obtained with the plates out of mesh by about 5mm - if the pointer on the knob is at 3 o'clock for fully meshed then it's at 4 o'clock for maximum deflection on 20m.

Nothing appears to be amiss in the PA cage, and although I haven't neutralised it since I fitted the PA valves a couple of years ago it was fine then and I don't see why it would have changed. The bias current is correct. I'm tuning into a 50 ohm dummy load with a short (20cm or so) pigtail with a UHF connector on the end.

Where should I start looking first? Since it behaves much the same on all bands is it possible that C17 (33pF, across one section of VC2) is open?

I believe there is a lot of confusion about what MV-203 is and why it is used in the Noise blanker gate driver transistor emitter and why would we be concerned about temperature stability device.

Part of the problem is that more than one manufacturer (TV set manufacturer included) used the same part number for different type of "diode". It would make no sense to me to use a Varactor in this application. .

Study the TS-830 noise blanker gate signal driver Q25 circuit and you may be able to figure it out. You will see 9vdc regulated is taken thru series resistor R96 820 ohm to shunt (diode, varactor, stabistor ????) to provide a regulated 2.2 vdc for the emitter of Q25.

The schematic shows 6.2vdc on the emitter of Q25 and that is true if the NB is turned off. If you turn on the NB and vary the NB control thru its range you will get a voltage of approx 0.10 vdc thru approx 2.2vdc at the emitter of Q25. Bring your soldering iron tip close to D25 (MV-203) and see what happens.

I contacted Kenwood Part several years ago and was told to use a MA27T-B which appears to be a Stabistor?

All of this has been hashed out on Eham and QRZ related to TS-440s in the past.

I have never seen a bad MV-203.

Terry K9TW

Steve,

  Yahoo.. sorry...GREAT! I recommend the dental floss trick when putting the slug back in. Re-install the slug while the can is still in your hand...
and see if it works...there should be some resistance to being turned. I have seen pieces of rubberband used for the same purpose but,
that doesn't seem to work on these small items

Glue trick worked!

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Steve,

Were you trying to turn them and they just went to the bottom?

It is NOT uncommon for this to happen. I've had it happen to me about 4-5 times on 530/830's

There are several methods: one is to use a very small amount of "super glue" on the very tip on the tuning tool,
   making sure the the tip goes into the slot...and the tool/tip remains vertical. You get glue between the slug and
the thin plastic insulation...you are in trouble!! Don rush..let the glue set up for a few minutes...then SLOWLY & CAREFULLY
rotate (counter-clockwise as seen from the front) the tool while applying slight up force...see if it comes up. Take your time...you may have to try the glue several times.

  The second is to unsolder the offending can
and you can insert your tuning tool in through the bottom and turn & push up to the
   the slug up and out. Take notes on the orientation...most will go back in only one way...but why push your luck.

 I like the second method better...super glue in a coil form scares the @*#$ outta me.

  Once the offending slug(s) are out you can use a small piece of waxed dental floss between the slug and the inside of the can
to take up some slack, and the wax on the floss acts as a lubricant.

Do not use any metal tool or tools on or around those tuning cores/slugs...they will get really mad and break...compounding your problem.
They also have slots on both ends...so they can be swapped end for end.

These are the two most common methods...good luck & GO SLOW

Joe,

The Lego tuning tool works very well. I got 10 MHZ to pop up to an S5 adjusting the rear, then i went to the front coil and it wasnt doing anything. I re re checked to make sure I was on the right coil. but it just stayed at the bottom of the can. I went back to the first coil and without much effort, the slug slipped to the bottom. So now I have two slugs sitting on te bottom of the cans. Is there a way to push them back up? I was concering de solderin them to see if it was open on the bottom, then push them back up to the top. and then resoldering.

any experience with these?

steve

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

I have the rig apart, now. I am waiting on Kens couples before i power up again. The plastic coupler on the band switch is broke. i was able to tighten up a bit as the screws were loose as well. Then when i was going through it again, i noticed that one of the set screws was now hanging out...by a thread. (haha) so i pulled that screw out, others are loose because the plastic scratched. i dont want to risk having a screw fall out when 900 volts is on. so once that is fixed, i will clean the contacts again (also will swap out the resistors on the final board and change the driver) THEN I will start recking the alignment again . All looked pretty good with the cal signal all close to S9...except 10 MHZ , like I said was really low S2 or 3 i think.
I found a little plastic rod in my sons lego stuff. It fits down into the can nice. Its short, so I glued into a tube used from a can of compressed air. I will carve and file tomorrow and try for fit. where did you find the NOS tools at? Amazon, Ebay? does it have a name or part number?

Thanks porcupine

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Steve,

I have the 5 pc version...but I did get a real good deal on an NOS tv alignment set...this had everything I could possibly need,
especially some long shafted tools to get to some on the tuning coils...ie..T-4 on the 830

RF board...as this tool is
flexible.
It was actually rather cheap...$30.00.

  Gordon's method sounds fine...about heating the tool...I have not used that method...but I trust his judgement,,,he's been at
this a lot longer than I have..hihi. I have several different coil slugs that are found on/in the KW hybrids...I use them to "fine tune"
my exacto knife approach as the slugs are junk(broken in half)...and I can observe them under my magnified light..remember...
use "decaf" coffee...those damn blades are sharp!

  I am shooting from the hip
here...as I don't have a schematic in front of me...but with all else being equal...there maybe
some "crud" on the associated band switch contact points...as the "cal signal" I believe is inserted after L-41..(antenna step xfmr)
so should eliminate that as a possible problem. What is the difference between the "S" meter readings? They will tend to decrease
as the band changes go higher in frequency...but should NOT fall off from say, "S-9" on 20M to "S-3" on 10M

  I do not want to steer you in the wrong direction...others here have WAY more diagnostic skills than I do...so, I shall reserve
my recommendation to what my limited knowledge allows me to do

   hey Mo.....

No Joe, I dont get a good cal sig on 30. most other bands are close to or at S9, Thats what makes me wonder if its not "something else"

There are two tool sets on amazon..one have 5 pc the other 12 (I think) which one did you get?

thanks

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Steve,

  I have used the "alignment tool set" from "Amazon" that your were talking about in your original post. The thing that you
will have to do is take a very sharp knife...say
an exacto...and trim back some of the plastic as the end is at times too short
to get to the slug, as the shoulder of the tool can hit on the top of the "can." Or, go to

a
hobby or craft store and look for a piece
of plastic rod that you can "custom" make your own...or a nice piece of dowel stock.

I do not know enough about the noise blanker circuit to offer a logical/correct answer. I think that Terry-k9tw, just answered
something about a noise blanker a few posts ago.

As far as 30m goes...check for proper adjustment of the associated coils first. Can you get a good "cal signal?"

Disconnecting the antenna is only reducing one of many paths lightning comes into the rig. I have seen many times at radio sites where lightning comes thru power and telephone lines to do it's damage. For instance , if you have a "modern" setup with a computer hooked to the radio, one path is thru the computer from your internet connections if it is TV cable and a modem. Lightning can hit a utility pole and come in thru the Power line, DSL or TV cable drop also.

My 93 year old mother-in-law informs me that lightning can also travel through telephone landlines and plumbing pipes -- which is why you should only use a cell phone while taking a shower during a thunderstorm.

While following mom's advice may help avoid personal injury, your expensive, often irreplaceable ham gear -- more importantly -- is ALWAYS in danger from lightning induced currents traveling electromagnetically from anywhere on the planet, even if your radios are unplugged from both antennae and power sources. Storing rigs in an inert state underground in a Faraday cage is just about the only realistic hope you have.

Remain vigilant. Never relax!

Yup...happened to me 2 years ago...a very intense lightning storm blew through Reno...one strike hit a telephone distribution box, 3 blocks from my house. The energy came through the phone lines and took out everything remotely connected to the line..TV's, Network, refrigerator, freezer, Even somehow took out both my HVAC systems in the house..and..oh yes, my TS-2000..has a hole burned through the main RF board, which Cliff, down in Texas at AVVid repaired (Replaced, actually. BTW, the board had the new filters but nothing else)

Phone company denied anything happened..ie: Not their fault....Insurance and then small claims convinced them otherwise....to the collective tune of over $15,000.00! Good thing I didn't go to district court..I imagine the punitive damages would have taken care of a pair or 3 new Kenwood super radios, TS-990S, with the amplifiers to go with them! Hmm..it's not too late.....isn't the statute of limitations 3 years, or is it 5 on damage claims? HMMMMMMMM Heh.

This is all true. I was only commenting about the antenna problem. Many times the antenna is the main lightning attracter because of it's height.

When I was in Az when a thunderstorm was in the area we shut all the computers and other sensitive electronics down and unplugged them from the wall.

On the Mt. Lemmon telescope I had the building wired with a large 4 phase knife switch. We disconnected all three incoming powerlines and the local earth ground. We had gas discharge clamps (600V) and semiconductor clamps (250V) on all the lines. All power was underground and once we took a hit directly to the powerhouse. We had two large (marine) standby generators. On of the generators took the direct hit.

Yes and that's how most lightning strikes damages occur, through the main power feed to the house. That's why it's very important to have ALL grounds, shack included, at the "same ground potential". This means if your shack has a separate ground outside the window or your shack is a separate building from the house, the grounds should all be connected to the house main ground.

My shack is separate from the house, 10 x 20 building in the back yard. Power to the shack is supplied through PVC pipe, 12 inches underground, from the house (electrician installed it). The electrician said I didn't need a ground at the shack because the heavy solid copper wire connecting the shack to the house ground was sufficient. I disagreed with him and said "put the ground rod in next to the shack and ground the shack panel to it". He said OK and did that. Doing this made the house and shack grounds at the same potential. I've had no problems even with lightning hit the 90 foot tall pine tree 15 feet from the shack.

Tom Rauch, W8JI, has a very good and informative webpage on grounding and lightning. I highly recommend taking some time and read/review his webpages on grounding. My shack is grounded the same way Tom's website illustrations show.

Joe, W7RKN,
Yup, happened to me , too!
Have a 185' Long-Wire hooked directly to my MFJ tuner.
Lightning struck out in the trees behind my house.
The Long-Wire captured enough of the Electro Impulse
that it burned out the diodes and transistor meter circuits.

A full disconnect is required.
I use an Antenna Switch with a ground select for the Tuner.

Years back, working in a down-building, 7 stories tall, lightning struck a rain gutter, arced across to a window screen, arced into and touched a printer which was wired directly to the I.T. server farm. Burned out 7 servers. We had put supressors on all the power lines, and all the T-10 lines to the terminals.
But Lightning found a "back-door". That was worth $250K per day in lost business.

"Watch Your Back" has taken on a New Meaning in Ham Radio !

I forgot to mention if you look at D22 (MV-203) symbol you will see it looks like 2 silicon diodes in series and not a varactor diode. Kenwood uses the traditional varactor diode symbol quite appropriately for the RIT diode in the VFO.

Have to ask yourself what level of precision is required for Q25 emitter voltage? How precise a reference is necessary for NB gate driver?

Also I dont think there is a reason and no room to install a band gap TL431 reference at the D22 location.

In a pinch to replace a bad MV-203 "zener" diode and restore the TS830 Noise Blanker you can just use a Orange or Yellow LED as a 2.0vdc to 2.2vdc reference source.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

I believe there is a lot of confusion about what MV-203 is and why it is used in the Noise blanker gate driver transistor emitter and why would we be concerned about temperature stability device.

Part of the problem is that more than one manufacturer (TV set manufacturer included) used the same part number for different type of "diode". It would make no sense to me to use a Varactor in this application. .

Study the TS-830 noise blanker gate signal driver Q25 circuit and you may be able to figure it out. You will see 9vdc regulated is taken thru series resistor R96 820 ohm to shunt (diode, varactor, stabistor ????) to provide a regulated 2.2 vdc for the emitter of Q25.

The schematic shows 6.2vdc on the emitter of Q25 and that is true if the NB is turned off. If you turn on the NB and vary the NB control thru its range you will get a voltage of approx 0.10 vdc thru approx 2.2vdc at the emitter of Q25. Bring your soldering iron tip close to D25 (MV-203) and see what happens.

I contacted Kenwood Part several years ago and was told to use a MA27T-B which appears to be a Stabistor?

All of this has been hashed out on Eham and QRZ related to TS-440s in the past.

I have never seen a bad MV-203.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

The MV-203 is a varactor diode, not a zener. Any stabilization that it would do would be in a voltage controlled frequency control loop, not in a voltage stabilizing circuit. The original MV-xxx numbers stood for Motorola Varactor.

IF there are small zeners that need some replacements that are hard to find, I recommend a replacement with TLVH431 3 terminal shunt regulators. These versatile devices with a couple of resistors work extremely well to make ideal zeners and they are adjustable with the right resistors from 1.24V up to about 37V. They are available in TO-92 packages making them simple to solder and TI can sample them if you go on their website. I have no affiliation with TI—they were a competitor of mine at one time. NXP has the same devices but not in TO-92. They are not very high current shunt regulators, but with a few more parts even that can be fixed.

Then perhaps the solution to that annotation in the files is to either remove it entire, or add a note to the thing about this NOT being needed.

I seem to recall (checked, yes it's there) that the note only applies to EARLY models of the 830, before a certain serial number, that were produced WITHOUT the MV-203 zener diode.

Which is what I identified the part as, by the way, a 2.2v ZENER, in the post that started this thread. NOT a varactor. Here is the note copied from the pdf file:

"Note:
Applies to any unit before serial: 2010000*, 1120950*, 1132058*"

If there is already an MV-203 in there, it obviously doesn't NEED one. If it is one of these lower serial numbers, and you're wanting to follow this tech note, then one or another of the cross-referenced diodes, can be used to substitute fot the MV-203.

Now, if some of the possible replacements I listed in the original post are actually varactors instead of zener diodes, that's the fault of the cross-reference I used. It is not intentional at all.

Is that what brought varactors into this in the first place? THAT is what is confusing me. I used a cross-reference database and copied the results into the message. I did NOT put every one of the results back in and pull up a complete data sheet to double-check.

If that is the problem, just say, "Part X is not a zener; it is not a correct replacement part," and go on from there.

Mea Maxima Culpa.

I think that if the pdf file on this (to see the serial number limitations) and the original post (which says that the part needed is a '2.2v zener') were actually -read-, there might be less confusion ongoing.

The thing is Kenny, to be an old time CB'er you needed no exam and were limited to about 5 watts (legally)
on the 27 Mhz band. Comparing it to the idea of "proper" Ham radio is rather like comparing a Cessna
to a Eurofighter.
The whole original idea of Ham radio was to train people in radio technology and allow them to transmit
on what was then considered less useful frequencies. It was expected that most Hams would build at least
some of their own equipment.
CB was simply about the ancient equivalent of texting.

Terry,

In looking over the NB circuit it seems that D22 in the service manual (Revised Edition) is listed as an MV-13 which is a 1.2V nominal zener type device. R96 in this schematic is 2.2K.

The problem I'm having is the diode symbol which shows the cathode at ground and the anode driven by current through R96. In otherwords it is forward biased instead of in zener breakdown according to the symbol used. It shows 2 diode arrows in series which is what you would have for voltage at 1.2V. It does not seem that the device would apply an emitter bias of 2.2V in this version of the schematic so depending on the revision perhaps this circuit was modified over the course of the product cycle.

My take on the circuit is that when off, 6.2V at the emitter of Q25 holds that device completely off even with a large noise spike at its base. When on, the threshold voltage to turn Q25 on is determined by the potentiomer that is fed by the diode stabilizer in question. This is a relatively low voltage compared to 6.2V so a small noise pulse would turn on Q25 to drive the noise gate. The pot sets the threshold and a decently stabilized voltage would keep the threshold steady. Temperature effects at Q25 and at D22 would move this threshold around but without a lot of thinking on this it may be that there is temperature compensation inherent in the circuit. That's conjecture on my part and I could be wrong on temp effects.

At any rate an MV-203 varactor is not the device to be used in this circuit unless there was another zener device of the same type number. This would be a very big confusion and would render the circuit useless if the wrong type was used. This needs to be regulator device and depending on the revision seems to be either a 1.2V or 2.1V part. Several good options for replacements for either voltage.

Larry

I think your analysis is pretty close. You can see that 12vdc regulated is divided by the two 100k divider resistors to approx 6.0vdc. I have measured several TS-830 and I see approx 5.98vdc at Emitter of Q25 with NB turned Off. .

If you measure NBV terminal at Molex Conn 9 you will see 2.05vdc.

With NB turned On the voltage range at Emitter Q25 is 0.109vdc with level control full CW and 2.05vdc with level control full CCW. I have not measured Emitter current and may do that when I get some time.

So I believe that D22 is simply a nominal 2.0vdc "zener" of the early 1980s. I dont think it has anything to do with temperature stability. Traditional ways to temperature stabilize a transistor amp would include:
1. Swamping resistor from Q25 Emitter lead to ground to provide degen feedback
2. Thermistor from Q25 Base to grd
3. Forward biased diode from Base to ground.

I think in 1980s there was limited choice in a 2 vdc zener diode and I understand today not much better as the performance of the low voltage zeners I have read about is not good.

I think we agree that D22 isnt a varactor or a thermistor. Sure looks like it is serving as a "zener" to me.

Maybe it would be better to call it a "reverse" zener based on the symbol?

It may well be a Stabistor which has good stable forward voltage. That would explain the symbol. I understand that they do come with multiple series connected diodes inside a single package so that would also align with the symbol. With the 2.05 vdc that I have measured three anodes in the symbol would make more sense than two.

So instead of using a LED to replace it then just stack 3 silicon diodes in series for approx 2.1vdc? There is room to insert 3 series connected silicon diodes at D22 location on Audio board.

I have no experience with a Stabistor but seems to me would be ideal for transistor bias regulator circuit.

It amazes me that this topic never seems to die and so many opinions on what an MV203 is. As I said I found several different data sheets from different mfg including one that was for a varactor diode. I have seen on other forums where posters have stated pretty emphatically that it is a varactor in the involved Kenwood rig including non Hybrids.

I have not found been able to find the MA27T-B diode yet. If you locate would be interested in what it is.

I am not criticizing any thing you wrote.

It is just old news and agree should be cleared up, but doubt any sense of urgency to do so. Would hope would be addressed when and if someone has a failed one. I did not detect that you had a bad D22 and was asking what was the sub for it?

There are numerous things in the Files Section that need removed or cleared up. Havent got the time or energy to begin typing that list. As some one said because it is said or written does not make it so. Have to evaluate all based on does it make sense to you and when it does not then surely ask. Asking at time of need might be better use of resources?

I am just trying to say it is not a Varactor diode even though you can clearly find MV-203 data sheets for Varactor diodes which has led some folks on other forums to insist it is a Varactor.

I am saying that I believe it is a Stabistor and not technically a Zener diode, but serves same purpose to provide regulated lower voltage from a higher voltage.

I just wish people would look at circuits and attempt to analyze them in order to determine the what and why related to component selection and config. OK to look up the part number and look at the data sheet and the app notes, but once you have done that does any of that make sense based on your understanding of the circuit.

Perhaps at one time there was a MV-203 Stabistor or perhaps it is just a typo?

I bet if you looked at the licence issue dates, you'd see a huge bump in the early-to-mid-80s as people got bored with CB and moved onto bigger and louder toys.

Certainly my late father Ralph GM0EXW got both his B and A licence at roughly the same time as a group of people he knew from his interest in the (old, illegal AM) CB scene. 27MHz wasn't doing it, so it was time to get a licence and use 7MHz instead. That's round about when my interest in the hobby started too, but my mum made it quite clear that I'd be far better off studying for school instead of any amateur radio licence, particularly if I wanted to eat my dinner in the house ;-)

I do sometimes wonder if I'd get quite so much of the "Oh you've got an M callsign so you must have just heard about radio last week, you stupid kid" attitude from people old enough to know better if I re-activate my dad's old GM0 callsign.

This may not be helpful, and I apologize if that is the case, but the term “portable” should not really be used with any rig that has a built in power supply: TS-930S, TS-850S, TS-940S, etc. I have the TS-930S and when I think of going portable, it comes in near the bottom of the list just before my Drake TR4C. I’ve had a TS-940 and, as I remember, it was heavier than the ‘930S.

Again, just my knee-jerk reaction.

True enough, David. Along those same lines, my parents had a GE "portable" TV back in the late 50's. The magazine advertisement for this model showed a pert young lady merrily transporting this thing easily by way of the handy, dandy built-in handle on the top of the stylish two-tone red and cream colored cabinet.

The ad bragged that "It's amazing enough that the General Electric Big Screen Portable is so light. Just 32 pounds so it's easy to carry wherever you want..."

Well, like my 32 pound TS-830S, it felt more like 75 pounds after a minute or two.

I left the tweakier glued to the slug untill i got max signal, then detached it and did the other..then very gently tweeked the first. i didnt remove them. i am hoping they are high enough that they are getting a good bite now on the threads. I have thought about putting a drop of wax down there..but dont want to temp fate. i got my new brass couplers in from Ken. If anything, they are shipping fast now. so now i need to stop at the hardware store and get a long allen wrench. then once the and switch is in, ill put in the new cathode resistors..and hopefully I'll be set for the winter.... cruising the NEW warc bands. LOL

or maybe ill listen to 3 guys talking to a Nazi sub who wants to be taken over by remote control.

Glue trick worked!

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Steve,

Were you trying to turn them and they just went to the bottom?

It is NOT uncommon for this to happen. I've had it happen to me about 4-5 times on 530/830's

There are several methods: one is to use a very small amount of "super glue" on the very tip on the tuning tool,
making sure the the tip goes into the slot...and the tool/tip remains vertical. You get glue between the slug and
the thin plastic insulation...you are in trouble!! Don rush..let the glue set up for a few minutes...then SLOWLY & CAREFULLY
rotate (counter-clockwise as seen from the front) the tool while applying slight up force...see if it comes up. Take your time...you may have to try the glue several times.

The second is to unsolder the offending can and you can insert your tuning tool in through the bottom and turn & push up to the
the slug up and out. Take notes on the orientation...most will go back in only one way...but why push your luck.

I like the second method better...super glue in a coil form scares the @*#$ outta me.

Once the offending slug(s) are out you can use a small piece of waxed dental floss between the slug and the inside of the can
to take up some slack, and the wax on the floss acts as a lubricant.

Do not use any metal tool or tools on or around those tuning cores/slugs...they will get really mad and break...compounding your problem.
They also have slots on both ends...so they can be swapped end for end.

These are the two most common methods...good luck & GO SLOW

Joe,

The Lego tuning tool works very well. I got 10 MHZ to pop up to an S5 adjusting the rear, then i went to the front coil and it wasnt doing anything. I re re checked to make sure I was on the right coil. but it just stayed at the bottom of the can. I went back to the first coil and without much effort, the slug slipped to the bottom. So now I have two slugs sitting on te bottom of the cans. Is there a way to push them back up? I was concering de solderin them to see if it was open on the bottom, then push them back up to the top. and then resoldering.

any experience with these?

steve

I have the rig apart, now. I am waiting on Kens couples before i power up again. The plastic coupler on the band switch is broke. i was able to tighten up a bit as the screws were loose as well. Then when i was going through it again, i noticed that one of the set screws was now hanging out...by a thread. (haha) so i pulled that screw out, others are loose because the plastic scratched. i dont want to risk having a screw fall out when 900 volts is on. so once that is fixed, i will clean the contacts again (also will swap out the resistors on the final board and change the driver) THEN I will start recking the alignment again . All looked pretty good with the cal signal all close to S9...except 10 MHZ , like I said was really low S2 or 3 i think.
I found a little plastic rod in my sons lego stuff. It fits down into the can nice. Its short, so I glued into a tube used from a can of compressed air. I will carve and file tomorrow and try for fit. where did you find the NOS tools at? Amazon, Ebay? does it have a name or part number?

Thanks porcupine

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Steve,

I have the 5 pc version...but I did get a real good deal on an NOS tv alignment set...this had everything I could possibly need,
especially some long shafted tools to get to some on the tuning coils...ie..T-4 on the 830 RF board...as this tool is flexible.
It was actually rather cheap...$30.00.

Gordon's method sounds fine...about heating the tool...I have not used that method...but I trust his judgement,,,he's been at
this a lot longer than I have..hihi. I have several different coil slugs that are found on/in the KW hybrids...I use them to "fine tune"
my exacto knife approach as the slugs are junk(broken in half)...and I can observe them under my magnified light..remember...
use "decaf" coffee...those damn blades are sharp!

I am shooting from the hip here...as I don't have a schematic in front of me...but with all else being equal...there maybe
some "crud" on the associated band switch contact points...as the "cal signal" I believe is inserted after L-41..(antenna step xfmr)
so should eliminate that as a possible problem. What is the difference between the "S" meter readings? They will tend to decrease
as the band changes go higher in frequency...but should NOT fall off from say, "S-9" on 20M to "S-3" on 10M

I do not want to steer you in the wrong direction...others here have WAY more diagnostic skills than I do...so, I shall reserve
my recommendation to what my limited knowledge allows me to do

hey Mo.....

No Joe, I dont get a good cal sig on 30. most other bands are close to or at S9, Thats what makes me wonder if its not "something else"

There are two tool sets on amazon..one have 5 pc the other 12 (I think) which one did you get?

thanks

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Steve,

I have used the "alignment tool set" from "Amazon" that your were talking about in your original post. The thing that you
will have to do is take a very sharp knife...say an exacto...and trim back some of the plastic as the end is at times too short
to get to the slug, as the shoulder of the tool can hit on the top of the "can." Or, go to a hobby or craft store and look for a piece
of plastic rod that you can "custom" make your own...or a nice piece of dowel stock.

I do not know enough about the noise blanker circuit to offer a logical/correct answer. I think that Terry-k9tw, just answered
something about a noise blanker a few posts ago.

As far as 30m goes...check for proper adjustment of the associated coils first. Can you get a good "cal signal?"

I had good luck with joes advice on using some super glue on the tip of the tuning tool, and carefully inserting it into the slug's slot. waited longer than normal for the glue to cure, then slowly pull and turn up until the slug came up the can. i also looked at taking the RF board out, but decided that might lead to more problems. I now have 30 meters again.

The three gents who wanted 'em, check your email.

If the SASE is already on the way, ignore the email. Expect the diodes sent to you the day the envelope arrives. No problem turning it around the same day, they're not exactly tedious to handle...

Terry, if you send me an envelope, I will drop the extras to you in it. Otherwise I'll send them to you at the address listed in the FCC database some time next week early at my expense. (One whole 1st class stamp and an envelope, not exactly a burden.)

Wasting time trying to figure out the problem????? Trying to figure out a problem is how you learn. It is never a waste of time !
Wasting time is randomly pushing buttons or probing with a VOM without starting troubleshooting by reading the manuals !
Wasting time is griping about not getting help when you don't understand, instead of listening to advice on how the circuits that are bad are supposed to work.
The last is wasting all who read the posts' time.

Newbies might ask the questions because the want adivise from those more experienced i. Some may ask the questions so they do not have to waste time trying to figure out the problem. It might be a simple solution to the problem.

You do not need test equipment to be in the radio hobby.

Hey Guys,
Just a word to the wise. I recently installed the shaft couplers from Ken in my 830S and was having some issues until I realized that the original nylon couplers used metric set screws and Ken's use SAE. Fortunately I had just purchased a 25 piece Metric/SAE allen wrench set from Harbour Freight for under $10 which made the process fairly easy. Hope I have saved you some frustration.

I left the tweakier glued to the slug untill i got max signal, then detached it and did the other..then very gently tweeked the first. i didnt remove them. i am hoping they are high enough that they are getting a good bite now on the threads. I have thought about putting a drop of wax down there..but dont want to temp fate. i got my new brass couplers in from Ken. If anything, they are shipping fast now. so now i need to stop at the hardware store and get a long allen wrench. then once the and switch is in, ill put in the new cathode resistors..and hopefully I'll be set for the winter.... cruising the NEW warc bands. LOL

  or maybe ill listen to 3 guys talking to a Nazi sub who wants to be taken over by remote control.

Glue trick worked!
---In TS-520_820_530_830@...m, <ts-520_820_530_830@yahoogroups.com> wrote:
Steve,Were you trying to turn them and they just went to the bottom?It is NOT uncommon for this to happen. I've had it happen to me about 4-5 times on 530/830'sThere are several methods: one is to use a very small amount of "super glue" on the very tip on the tuning tool,   making sure the the tip goes into the slot...and the tool/tip remains vertical. You

get glue between the slug andthe thin plastic insulation...you are in trouble!! Don rush..let the glue set up for a few minutes...then SLOWLY & CAREFULLYrotate (counter-clockwise as seen from the front) the tool while applying slight up force...see if it comes up. Take your time...you may have to try the glue several times. The second is to unsolder the offending can and you can insert your tuning tool in through the bottom and turn & push up to the the slug up and out. Take notes on the orientation...most will go back in only one way...but why push your luck. I like the second method better...super glue in a coil form scares the @*#$ outta me. Once the offending slug(s) are out you can use a small piece of waxed dental floss between the slug and the inside of the canto take up some slack, and the wax on the floss acts as a lubricant. Do not use any metal tool or tools on or around those tuning cores/slugs...they will get really mad and break...compounding your problem. They also have slots on both ends...so they can be swapped end for end. These are the two most common methods...good luck & GO SLOW

Joe,

The Lego tuning tool works very well. I got 10 MHZ to pop up to an S5 adjusting the rear, then i went to the front coil and it wasnt doing anything. I re re checked to make sure I was on the right coil. but it just stayed at the bottom of the can. I went back to the first coil and without much effort, the slug slipped to the bottom. So now I have two slugs sitting on te bottom of the cans. Is there a way to push them back up? I was concering de solderin them to see if it was open on the bottom, then push them back up to the top. and then resoldering.

any experience with these?

steve

I have the rig apart, now. I am waiting on Kens couples before i power up again. The plastic coupler on the band switch is broke. i was able to tighten up a bit as the screws were loose as well. Then when i was going through it again, i noticed that one of the set screws was now hanging out...by a thread. (haha) so i pulled that screw out, others are loose because the plastic scratched. i dont want to risk having a screw fall out when 900 volts is on. so once that is fixed, i will clean the contacts again (also will swap out the resistors on the final board and change the driver) THEN I will start recking the alignment again . All looked pretty good with the cal signal all close to S9...except 10 MHZ , like I said was really low S2 or 3 i think.
I found a little plastic rod in my sons lego stuff. It fits down into the can nice. Its short, so I glued into a tube used from a can of compressed air. I will carve and file tomorrow and try for fit. where did you find the NOS tools at? Amazon, Ebay? does it have a name or part number?

Thanks porcupine

No Joe, I dont get a good cal sig on 30. most other bands are close to or at S9, Thats what makes me wonder if its not "something else"

There are two tool sets on amazon..one have 5 pc the other 12 (I think) which one did you get?

thanks

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:
Steve, I have used the "alignment tool set" from "Amazon" that your were talking about in your original post. The thing that youwill have to do is take a very sharp knife...say an exacto...and trim back some of the plastic as the end is at times too short to get to the slug, as the shoulder of the tool can hit on the top of the "can." Or, go to a hobby or craft store and look for a pieceof plastic rod that you can "custom" make your own...or a nice piece of dowel stock. I do not know enough about the noise blanker circuit to offer a logical/correct answer. I think that Terry-k9tw, just answeredsomething about a noise blanker a few posts ago.As far as 30m goes...check for proper adjustment of the associated coils first. Can you get a good "cal signal?"

In the UK amateurs with Foundation licences (M3/M6 calls) aren't allowed to operate homebrew transmitters (but you can use one built from a commercial kit). In order to get the Intermediate licence you *must* build an operable radio-related project. There's nothing to say what it has to be or how complex, but most people I know have built one of the many SDR kits or a QRP transceiver kit. I know one local(-ish) amateur who transmits *less* since he passed his Intermediate, and spends most of his time playing with regenerative HF receivers since he got the bug by building one from a magazine article for his Intermediate project - I guess it's true, we do learn more by listening.

Of course there's another amateur I hear (and talk to) who has been a commercial HF op for years, and having retired is quite content to stuff his licence limit 10W into the horking great rhombic he has up. From the opposite end of the UK he is just about the loudest guy on 40m. Wouldn't it be nice to have the space to get that much wire up?

The thing is Kenny, to be an old time CB'er you needed no exam and were limited to about 5 watts (legally)
on the 27 Mhz band. Comparing it to the idea of "proper" Ham radio is rather like comparing a Cessna
to a Eurofighter.
The whole original idea of Ham radio was to train people in radio technology and allow them to transmit
on what was then considered less useful frequencies. It was expected that most Hams would build at least
some of their own equipment.
CB was simply about the ancient equivalent of texting.

Sorry forgot the data sheet for the 1N4157 diode

http://www.littlediode.com/datasheets/pdf/Datasheets-1N4/1N4157.PDF
http://www.littlediode.com/datasheets/pdf/Datasheets-1N4/1N4157.PDF

Here is explanation of how 4 series connected silicon diodes can provide reasonable 2.8vdc regulated from 12vdc source up to approx 20ma load. So it would seem that two would provide approx 1.4vdc and 3 would provide approx 2.1vdc.

http://www-personal.engin.umd.umich.edu/~fmeral/ELECTRONICS%20II/01%25c3-Misc%20Notes/Diode%20Voltage%20Regulator.pdf http://www-personal.engin.umd.umich.edu/~fmeral/ELECTRONICS%20II/01%25c3-Misc%20Notes/Diode%20Voltage%20Regulator.pdf

I think pretty safe to assume that MV-203 is a Forward Regulator Diode or a Stabistor.

Google is our friend!

I just never pulled the string very hard as I say have never seen a bad one.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

I am not criticizing any thing you wrote.

It is just old news and agree should be cleared up, but doubt any sense of urgency to do so. Would hope would be addressed when and if someone has a failed one. I did not detect that you had a bad D22 and was asking what was the sub for it?

There are numerous things in the Files Section that need removed or cleared up. Havent got the time or energy to begin typing that list. As some one said because it is said or written does not make it so. Have to evaluate all based on does it make sense to you and when it does not then surely ask. Asking at time of need might be better use of resources?

I am just trying to say it is not a Varactor diode even though you can clearly find MV-203 data sheets for Varactor diodes which has led some folks on other forums to insist it is a Varactor.

I am saying that I believe it is a Stabistor and not technically a Zener diode, but serves same purpose to provide regulated lower voltage from a higher voltage.

I just wish people would look at circuits and attempt to analyze them in order to determine the what and why related to component selection and config. OK to look up the part number and look at the data sheet and the app notes, but once you have done that does any of that make sense based on your understanding of the circuit.

Perhaps at one time there was a MV-203 Stabistor or perhaps it is just a typo?

Terry K9TW

> Have to ask yourself what level of precision is required for Q25 emitter
> voltage? How precise a reference is necessary for NB gate driver?

Then perhaps the solution to that annotation in the files is to either remove it entire, or add a note to the thing about this NOT being needed.

I seem to recall (checked, yes it's there) that the note only applies to EARLY models of the 830, before a certain serial number, that were produced WITHOUT the MV-203 zener diode.

Which is what I identified the part as, by the way, a 2.2v ZENER, in the post that started this thread. NOT a varactor. Here is the note copied from the pdf file:

"Note:
Applies to any unit before serial: 2010000*, 1120950*, 1132058*"

If there is already an MV-203 in there, it obviously doesn't NEED one. If it is one of these lower serial numbers, and you're wanting to follow this tech note, then one or another of the cross-referenced diodes, can be used to substitute fot the MV-203.

Now, if some of the possible replacements I listed in the original post are actually varactors instead of zener diodes, that's the fault of the cross-reference I used. It is not intentional at all.

Is that what brought varactors into this in the first place? THAT is what is confusing me. I used a cross-reference database and copied the results into the message. I did NOT put every one of the results back in and pull up a complete data sheet to double-check.

If that is the problem, just say, "Part X is not a zener; it is not a correct replacement part," and go on from there.

Mea Maxima Culpa.

I think that if the pdf file on this (to see the serial number limitations) and the original post (which says that the part needed is a '2.2v zener') were actually -read-, there might be less confusion ongoing.

I used to put a layer of bond paper down in the hole, and then screw the slug down on to the paper. You only need a strip about an eighth of an inch wide for those smaller slugs and a quarter inch for the larger ones, as a rule.

45196. Curious about VOX with an MC-50 mic and TS-820

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-08 15:08:55 UTC

I'm not in front of my 820 right now and won't be home for several hours, but I've never tried VOX with my MC-50. How easy is that to set and what are the optimum settings?

Thanks to you guys as usual... and I tried to check in to the Hybrid Net Saturday - I just couldn't get through. I thought conditions were going to be good for me, but I wasn't heard, so I'll try to get through next time.

I have a TS440SAT which I use in the relatively confined space on my boat. It’s a great rig, 12 volt powered and IMHO ideal for portable.

Barry,

There are no "special" settings. Each operator can and should , adjust the 3 controls to fit the situation.

With rig tuned up on what ever band(license class dependent) ...into a dummy load(preferred)...mode switch to USB or LSB.. turn VOX switch to ON....in a normal voice level..and about 2 or so inches from microphone...turn UP the "VOX GAIN" until the transmitter is keyed...then adjust the "DELAY" so that after about about 0.5 to 1 second after you stop speaking...the transmitter is un-keyed...there is an "anti-vox" adjustment also. read the operators manual...and play with the various adjustments to suit YOUR needs. Just make sure to monitor your AGC level...and adjust that as necessary

Hey Guys,
Just a word to the wise. I recently installed the shaft couplers from Ken in my 830S and was having some issues until I realized that the original nylon couplers used metric set screws and Ken's use SAE. Fortunately I had just purchased a 25 piece Metric/SAE allen wrench set from Harbour Freight for under $10 which made the process fairly easy. Hope I have saved you some frustration.

I left the tweakier glued to the slug untill i got max signal, then detached it and did the other..then very gently tweeked the first. i didnt remove them. i am hoping they are high enough that they are getting a good bite now on the threads. I have thought about putting a drop of wax down there..but dont want to temp fate. i got my new brass couplers in from Ken. If anything, they are shipping fast now. so now i need to stop at the hardware store and get a long allen wrench. then once the and switch is in, ill put in the new cathode resistors..and hopefully I'll be set for the winter.... cruising the NEW warc bands. LOL

  or maybe ill listen to 3 guys talking to a Nazi sub who wants to be taken over by remote control.

Glue trick worked!
---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:
Steve, Were you trying to turn them and they just went to the bottom? It is NOT uncommon for this to happen. I've had it happen to me about 4-5 times on 530/830's There are several methods: one is to use a very small amount of "super glue" on the very tip on the tuning tool, making sure the the tip goes into the slot...and the tool/tip remains vertical. You get glue between the slug and the thin plastic insulation...you are in trouble!! Don rush..let the glue set up for a few minutes...then SLOWLY & CAREFULLY rotate (counter-clockwise as seen from the front) the tool while applying slight up force...see if it comes up. Take your time...you may have to try the glue several times. The second is to unsolder the offending can and you can insert your tuning tool in through the bottom and turn & push up to the the slug up and out. Take notes on the orientation...most will go back in only one way...but why push your luck. I like the second method better...super glue in a coil form scares the @*#$ outta me. Once the offending slug(s) are out you can use a small piece of waxed dental floss between the slug and the inside of the can to take up some slack, and the wax on the floss acts as a lubricant. Do not use any metal tool or tools on or around those tuning cores/slugs...they will get really mad and break...compounding your problem. They also have slots on both ends...so they can be swapped end for end. These are the two most common methods...good luck & GO SLOW

Joe,

The Lego tuning tool works very well. I got 10 MHZ to pop up to an S5 adjusting the rear, then i went to the front coil and it wasnt doing anything. I re re checked to make sure I was on the right coil. but it just stayed at the bottom of the can. I went back to the first coil and without much effort, the slug slipped to the bottom. So now I have two slugs sitting on te bottom of the cans. Is there a way to push them back up? I was concering de solderin them to see if it was open on the bottom, then push them back up to the top. and then resoldering.

any experience with these?

steve
---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:
I have the rig apart, now. I am waiting on Kens couples before i power up again. The plastic coupler on the band switch is broke. i was able to tighten up a bit as the screws were loose as well. Then when i was going through it again, i noticed that one of the set screws was now hanging out...by a thread. (haha) so i pulled that screw out, others are

loose because the plastic scratched. i dont want to risk having a screw fall out when 900 volts is on. so once that is fixed, i will clean the contacts again (also will swap out the resistors on the final board and change the driver) THEN I will start recking the alignment again . All looked pretty good with the cal signal all close to S9...except 10 MHZ , like I said was really low S2 or 3 i think.
I found a little plastic rod in my sons lego stuff. It fits down into the can nice. Its short, so I glued into a tube used from a can of compressed air. I will carve and file tomorrow and try for fit. where did you find the NOS tools at? Amazon, Ebay? does it have a name or part number?

Thanks porcupine
---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:
Steve,   I have the 5 pc version...but I did get a real good deal on an NOS tv alignment set...this had everything I could possibly need, especially some long shafted tools to get to some on the tuning coils...ie..T-4 on the 830 RF board...as this tool is flexible. It was actually rather cheap...$30.00.   Gordon's method sounds fine...about heating the tool...I have not used that method...but I trust his judgement,,,he's been at this a lot longer than I have..hihi. I have several different coil slugs that are found on/in the KW hybrids...I use them to "fine tune" my exacto knife approach as the slugs are junk(broken in half)...and I can observe them under my magnified light..remember... use "decaf" coffee...those damn blades are sharp!   I am shooting from the hip here...as I don't have a schematic in front of me...but with all else being equal...there maybe some "crud" on the associated band switch contact points...as the "cal signal" I believe
is inserted after L-41..(antenna step xfmr) so should eliminate that as a possible problem. What is the difference between the "S" meter readings? They will tend to decrease as the band changes go higher in frequency...but should NOT fall off from say, "S-9" on 20M to "S-3" on 10M   I do not want to steer you in the wrong direction...others here have WAY more diagnostic skills than I do...so, I shall reserve my recommendation to what my limited knowledge allows me to do   hey Mo.....

No Joe, I dont get a good cal sig on 30. most other bands are close to or at S9, Thats what makes me wonder if its not "something else"

There are two tool sets on amazon..one have 5 pc the other 12 (I think) which one did you get?

thanks

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:
Steve,   I have used the "alignment tool set" from "Amazon" that your were talking about in your original post. The thing that you will have to do is take a very sharp knife...say an exacto...and trim back some of the plastic as the end is at times too short to get to the slug, as the shoulder of the tool can hit on the top of the "can." Or, go to a hobby or craft store and look for a piece of plastic rod that you can "custom" make your own...or a nice piece of dowel stock. I do not know enough about the noise blanker circuit to offer a logical/correct answer. I think that Terry-k9tw, just answered something about a noise

blanker a few posts ago. As far as 30m goes...check for proper adjustment of the associated coils first. Can you get a good "cal signal?"

Hi guys,,,I dont know where my post went, maybe into the land of rare DX . Strange thing is I saw a reply last night, where someone suggested K4EAAs site..oh well....but I was wondering if anybody has seen where to get alignment tools for the 530s. Ken sells them for the 520, but not the 530.
Also the noise blanker isnt working. Any ideas.

Also 30 meters is very low on recieve, all other bands okay. anything there besides an alignment?

steve

45202. Connector 9

Hi All,
I am trying to fix a donated TS830 that has some display problems & a meter problem. The display is still intermittent & occasionally bright. I still have not found the cold solder joint(s). There is a crack or joint problem somewhere.

As I start tracing wires, I notice Connector 9 on the south top side of the IF board is disconnected. So I connect it & immediately lose all audio. I unplug it & the audio does not return. Now I have bigger fish to fry it looks like. As I look at the online schematics, I can find the connector but cannot read the the detail on either the rendition of the board or the schematic.

Any chance someone has a good pdf copy of both they could send?

Thanx much - 73 Bob V W8RMV

I ran into similar issues trying to remove a coupler in a TS-530 where a standard U.S. Precision Craft tool's Hex wrench wouldn't fit/work. The coupler's Hex set screw was obviously metric. I looked for and found a complete set of metric BONDHUS Hex wrenches which contained every metric size, including the 1.5mm Hex wrench, at my local hardware store. The Hex wrench tool set is made by BONDHUS tools.

There may be other metric sets available but the BONDHUS set is what I use which contains the 1.5mm hex wrench.

Go to Gordon's website and download the high resolution "color" TS-830
schematic pdf file.

Ron,

Are you for a fact looking at the "rectifier board" vs the "hv board?" as there are R-5's & R-6's on both.

What are the symptoms/complaints that you are inquiring about...and by "take out" ...do you mean..destroyed, broken
or just way high in value?

Hi Joe,
I'm glad that you're not having a problem. My 1.5MM slipped in the brass coupler and that's when I realized that Ken's couplers used SAE.

Butch, I had a doubt about this...so I checked...I have a couple of broken nylon ones(screws still there) and a couple of "Kens." There is a slight difference as you stated, but my long shaft 1.5MM allen wrench tool(ok...no jokes here)seems to work just fine on both

Hey Guys,
Just a word to the wise. I recently installed the shaft couplers from Ken in my 830S and was having some issues until I realized that the original nylon couplers used metric set screws and Ken's use SAE. Fortunately I had just purchased a 25 piece Metric/SAE allen wrench set from Harbour Freight for under $10 which made the process fairly easy. Hope I have saved you some frustration.

I left the tweakier glued to the slug untill i got max signal, then detached it and did the other..then very gently tweeked the first. i didnt remove them. i am hoping they are high enough that they are getting a good bite now on the threads. I have thought about putting a drop of wax down there..but dont want to temp fate. i got my new brass couplers in from Ken. If anything, they are shipping fast now. so now i need to stop at the hardware store and get a long allen wrench. then once the and switch is in, ill put in the new cathode

resistors..and hopefully I'll be set for the winter.... cruising the NEW warc bands. LOL

  or maybe ill listen to 3 guys talking to a Nazi sub who wants to be taken over by remote control.

Joe,

The Lego tuning tool works very well. I got 10 MHZ to pop up to an S5 adjusting the rear, then i went to the front coil and it wasnt doing anything. I re re checked to make sure I was on the right coil. but it just stayed at the bottom of the can. I went back to the first coil and without much effort, the slug slipped to the bottom. So now I have two

slugs sitting on te bottom of the cans. Is there a way to push them back up? I was concering de solderin them to see if it was open on the bottom, then push them back up to the top. and then resoldering.

any experience with these?

steve

Be aware that a couple of connectors can be swapped by mistake. ie..
they will both plug into the other, but that causes problems...LOL
I don't remember off hand if it is 8 & 9 or 11 & 12
Might want to double check them.
There is a "High Resolution" Service manual on my website that allows
you to zoom in pretty nice on the IF board.

Appears that filter capacitors C27 (backwards "D" terminal 22ufd 450VDC) for R5 and C28 (backwards "D" terminal 22ufd 450VDC) for R6 may be shorted internally. You can see this by reviewing the TS-520 schematic. These capacitors are located on the left rear below the VOX Unit and Marker Unit boards.

I ran into similar issues trying to remove a coupler in a TS-530 where a standard U.S. Precision Craft tool's Hex wrench wouldn't fit/work. The coupler's Hex set screw was obviously metric. I looked for and found a complete set of metric BONDHUS Hex wrenches which contained every metric size, including the 1.5mm Hex wrench, at my local hardware store. The Hex wrench tool set is made by BONDHUS tools.

There may be other metric sets available but the BONDHUS set is
what I use which contains the 1.5mm hex wrench.

>Steve, Were you trying to turn them and they just went to the bottom? It is NOT uncommon for this to happen. I've had it happen to me about 4-5 times on 530/830's There are several methods: one is to use a very small amount of "super glue" on the very tip on the tuning tool, making sure the the tip goes into the slot...and the tool/tip remains vertical. You get glue between the slug and the thin plastic insulation...you are in trouble!! Don rush..let the glue set up for a few minutes...then SLOWLY & CAREFULLY rotate (counter-clockwise as seen from the front) the tool while applying slight up force...see if it comes up. Take your time...you may have to try the glue several times. The second is to unsolder the offending can and you can insert your tuning tool in through the bottom and turn & push up to the the slug up and out. Take notes on the orientation...most will go back in only one way...but why push your luck. I like the second method better...super glue in a coil form scares the @*#$ outta me. Once the offending slug(s) are out you can use a small piece of waxed dental floss between the slug and the inside of the can to take up some slack, and the wax on the floss acts as a lubricant. Do not use any metal tool or tools on or around those tuning cores/slugs...they will get really mad and break...compounding your problem. They also have slots on both ends...so they can be swapped end for end. These are the two most common methods...good luck & GO SLOW

>The Lego tuning tool works very well. I got 10 MHZ to pop up to an S5 adjusting the rear, then i went to the front coil and it wasnt doing anything. I re re checked to make sure I was on the right coil. but it just stayed at the bottom of the can. I went back to the first coil and without much effort, the slug slipped to the bottom. So now I have two slugs sitting on te bottom of the cans. Is there a way to push them back up? I was concering de solderin them to see if it was open on the bottom, then push them back up to the top. and then resoldering.

wrote:
>I have the rig apart, now. I am waiting on Kens couples before i power up again. The plastic coupler on the band switch is broke. i was able to tighten up a bit as the screws were loose as well. Then when i was going through it again, i noticed that one of the set screws was now hanging out...by a thread. (haha) so i pulled that screw out, others are loose because the plastic scratched. i dont want to risk having a screw fall out when 900 volts is on. so once that is fixed, i will clean the contacts again (also will swap out the resistors on the final board and change the driver) THEN I will start recking the alignment again . All looked pretty good with the cal signal all close to S9...except 10 MHZ , like I said was really low S2 or 3 i think.
>I found a little plastic rod in my sons lego stuff. It fits down into the can nice. Its short, so I glued into a tube used from a can of compressed air. I will carve and file tomorrow and try for fit. where did you find the NOS tools at? Amazon, Ebay? does it have a name or part number?

>Steve,   I have the 5 pc version...but I did get a real good deal on an NOS tv alignment set...this had everything I could possibly need, especially some long shafted tools to get to some on the tuning coils...ie..T-4 on the 830 RF board...as this tool is flexible. It was actually rather cheap...$30.00.   Gordon's method sounds fine...about heating the tool...I have not used that method...but I trust his judgement,,,he's been at this a lot longer than I have..hihi. I have several different coil slugs that are found on/in the KW hybrids...I use them to "fine tune" my exacto knife approach as the slugs are junk(broken in half)...and I can observe them under my magnified light..remember... use "decaf" coffee...those damn blades are sharp!   I am shooting from the hip here...as I don't have a schematic in front of me...but with all else being equal...there maybe some "crud" on the associated band switch contact points...as the "cal signal" I believe
is inserted after L-41..(antenna step xfmr) so should eliminate that as a possible problem. What is the difference between the "S" meter readings? They will tend to decrease as the band changes go higher in frequency...but should NOT fall off from say, "S-9" on 20M to "S-3" on 10M   I do not want to steer you in the wrong direction...others here have WAY more diagnostic skills than I do...so, I shall reserve my recommendation to what my limited knowledge allows me to do   hey Mo.....

>Steve,   I have used the "alignment tool set" from "Amazon" that your were talking about in your original post. The thing that you will have to do is take a very sharp knife...say an exacto...and trim back some of the plastic as the end is at times too short to get to the slug, as the shoulder of the tool can hit on the top of the "can." Or, go to a hobby or craft store and look for a piece of plastic rod that you can "custom" make your own...or a nice piece of dowel stock. I do not know enough about the noise blanker circuit to offer a logical/correct answer. I think that Terry-k9tw, just answered something about a noise blanker a few posts ago. As far as 30m goes...check for proper adjustment of the associated coils first. Can you get a good "cal signal?"

Joe and Ron,

I think Ron's looking at the Rectifier Unit's R5 and R6. If R5 and R6 overheat/crack or otherwise fail, it's most likely due to C27 and C28 have shorted internally.

Ron, I also would check D5 and D6 both on the Rectifier Unit. If R5 and R6 on the Rectifier Unit failed due to C27 and C28 shorting internally then more than likely D5 and D6 are also bad, become open. If you measure the voltage at the Rectifier Unit's "210A" and "300A" and at the Junction of D5/R5 and D6/R6 and the voltage at both places is zero then diodes D5 and D6 are open.

C27 and C28 are multiple can capacitors, difficult to find replacements. Most people use individual axial or radial lead capacitor as replacements.

Gordon & group,

  Gordon, you are correct on both counts.....8 & 9 and 11& 12 could possibly be swapped by mistake,

    Connector #8 should be: blue, brown, yellow, orange, red wires

    Connector#11 should be: violet, violet, black, white wires.

    The color of the wires are the ones that are right at the connector...note: that on connectors 11, 12, & 9, the wires change
color just prior to getting to the connector. That's why it's a real good idea to mark the connectors or... document is some other way.

Be aware that a couple of connectors can be swapped by mistake. ie.. they will both plug into the other, but that causes problems...LOL
I don't remember off hand if it is 8 & 9 or 11 & 12
Might want to double check them.
There is a "High Resolution" Service manual on my website that
allows you to zoom in pretty nice on the IF board.

Barry,

There are no "special" settings. Each operator can and should , adjust the 3 controls to fit the situation.

With rig tuned up on what ever band(license class dependent) ...into a dummy load(preferred)...mode switch to USB or LSB.. turn VOX switch to ON....in a normal voice level..and about 2 or so inches from microphone...turn UP the "VOX GAIN" until the transmitter is keyed...then adjust the "DELAY" so that after
about about 0.5 to 1 second after you stop speaking...the transmitter is un-keyed...there is an "anti-vox" adjustment also. read the operators
manual...and play with the various adjustments to suit YOUR needs. Just make sure to monitor your AGC level...and adjust that as necessary

Joe & et al,
Thank you for this detail. Well the connectors are in the right places based on the new info. And after letting the 830 sit for awhile, the audio is back!! But as soon as I plug in #9 again it goes deaf. So the "simple" display & meter repairs have morphed into a lot more.

I am trying to d/l the HD SM but it is slow. The schematic came right thru. Looks like #9 (SSB,SM,VX1,G,RB2) connects to the audio board. More investigation!

Thanx again TO all who pitched in. 73 Bob V W8RMV

Hi Marshall,
This is the Best one I have.
http://www.n6wk.com/kenwood/TS-530S_Service.pdf
It's around 17 megs in size. but is the whole Service manual. The
schematic blows up well in this one.
I do not have a separate Schematic for the 530 like the one for the 830.

Here is what I think would replace your failed TS-830 D22 or your TS-530 D20 whether it is a speced as a MV-203 or MV-13 Stabistor.

Read the Design Data for explanation of what it is and how it works. Look at Table 2 at 1ma current and you can see that it will provide the 2.05 vdc NBV voltage that I have measured on more than one TS-830. I have not measured NBV on working TS-530.

I have not performed an exhaustive search but I believe that this device is obsolete? NTE calls out a NTE-177 silicon diode as a sub and that wont work unless you series them.

So if D20 or D22 has failed on your rig and you cant find a 1n4157 I would experiment with an orange LED or series string of silicon diodes.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

I am not criticizing any thing you wrote.

It is just old news and agree should be cleared up, but doubt any sense of urgency to do so. Would hope would be addressed when and if someone has a failed one. I did not detect that you had a bad D22 and was asking what was the sub for it?

There are numerous things in the Files Section that need removed or cleared up. Havent got the time or energy to begin typing that list. As some one said because it is said or written does not make it so. Have to evaluate all based on does it make sense to you and when it does not then surely ask. Asking at time of need might be better use of resources?

I am just trying to say it is not a Varactor diode even though you can clearly find MV-203 data sheets for Varactor diodes which has led some folks on other forums to insist it is a Varactor.

I am saying that I believe it is a Stabistor and not technically a Zener diode, but serves same purpose to provide regulated lower voltage from a higher voltage.

I just wish people would look at circuits and attempt to analyze them in order to determine the what and why related to component selection and config. OK to look up the part number and look at the data sheet and the app notes, but once you have done that does any of that make sense based on your understanding of the circuit.

Perhaps at one time there was a MV-203 Stabistor or perhaps it is just a typo?

Then perhaps the solution to that annotation in the files is to either remove it entire, or add a note to the thing about this NOT being needed.

I seem to recall (checked, yes it's there) that the note only applies to EARLY models of the 830, before a certain serial number, that were produced WITHOUT the MV-203 zener diode.

Which is what I identified the part as, by the way, a 2.2v ZENER, in the post that started this thread. NOT a varactor. Here is the note copied from the pdf file:

"Note:
Applies to any unit before serial: 2010000*, 1120950*, 1132058*"

If there is already an MV-203 in there, it obviously doesn't NEED one. If it is one of these lower serial numbers, and you're wanting to follow this tech note, then one or another of the cross-referenced diodes, can be used to substitute fot the MV-203.

Now, if some of the possible replacements I listed in the original post are actually varactors instead of zener diodes, that's the fault of the cross-reference I used. It is not intentional at all.

Is that what brought varactors into this in the first place? THAT is what is confusing me. I used a cross-reference database and copied the results into the message. I did NOT put every one of the results back in and pull up a complete data sheet to double-check.

If that is the problem, just say, "Part X is not a zener; it is not a correct replacement part," and go on from there.

Mea Maxima Culpa.

I think that if the pdf file on this (to see the serial number limitations) and the original post (which says that the part needed is a '2.2v zener') were actually -read-, there might be less confusion ongoing.

Hi Marshall,
 This is the Best one I have. http://www.n6wk.com/kenwood/TS-530S_Service.pdf
It's around 17 megs in size. but is the whole Service manual. The schematic blows up well in this one.
I do not have a separate Schematic for the 530 like the one for the 830.

Hey Guys,
Just a word to the wise. I recently installed the shaft couplers from Ken in my 830S and was having some issues until I realized that the original nylon couplers used metric set screws and Ken's use SAE. Fortunately I had just purchased a 25 piece Metric/SAE allen wrench set from Harbour Freight for under $10 which made the process fairly easy. Hope I have saved you some frustration.

I left the tweakier glued to the slug untill i got max signal, then detached it and did the other..then very gently tweeked the first. i didnt remove them. i am hoping they are high enough that they are getting a good bite now on the threads. I have thought about putting a drop of wax down there..but dont want to temp fate. i got my new brass couplers in from Ken. If anything, they are shipping fast now. so now i need to stop at the hardware store

and get a long allen wrench. then once the and switch is in, ill put in the new cathode resistors..and hopefully I'll be set for the winter.... cruising the NEW warc bands. LOL

or maybe ill listen to 3 guys talking to a Nazi sub who wants to be taken over by remote control.

Glue trick worked!
---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:
Steve, Were you trying to turn them and they just went to the bottom? It is NOT uncommon for this to happen. I've had it happen to me about 4-5 times on 530/830's There are several methods: one is to use a very small amount of "super glue" on the very tip on the tuning tool, making sure the the tip goes into the slot...and the tool/tip remains vertical. You get glue between the slug and the thin plastic insulation...you are in trouble!! Don rush..let the glue set up for a few minutes...then SLOWLY & CAREFULLY rotate (counter-clockwise as seen from the front) the tool while applying slight up force...see if it comes up. Take your time...you may have to try the glue several times. The second is to unsolder the offending can and you can insert your tuning tool in through the bottom and turn & push up to the the slug up and out. Take notes on the orientation...most will go back in only one way...but why push your luck. I like the second method better...super glue in a coil form scares the @*#$ outta me. Once the offending slug(s) are out you can use a small piece of waxed dental floss between the slug and the inside of the can to take up some slack, and the wax on the floss acts as a lubricant. Do not use any metal tool or tools on or around those tuning cores/slugs...they will get really mad and break...compounding your problem. They also have slots on both ends...so they can be swapped end for end. These are the two most common methods...good luck & GO SLOW

73 Joe WB7UQU

Joe,

The Lego tuning tool works very well. I got 10 MHZ to pop up to an S5 adjusting the rear, then i went to the front coil and it wasnt doing anything. I re re checked to make sure I was on the right coil. but it just stayed at the bottom of the can. I went back to the first coil and without much effort, the slug slipped to the bottom. So now I have two slugs sitting on te bottom of the cans. Is there a way to push them back up? I was concering de solderin them to see if it was open on the bottom, then push them back up to the top. and then resoldering.

any experience with these?

steve
---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote: I have the rig apart, now. I am waiting on Kens couples before i power up again. The plastic coupler on the band switch is broke. i was able to tighten up a bit as the screws were loose as well. Then when i was going through it again, i noticed that one of the set screws was now hanging out...by a thread. (haha) so i pulled that screw out, others are loose because the plastic scratched. i dont want to risk having a screw fall out when 900 volts is on. so once that is fixed, i will clean the contacts again (also will swap out the resistors on the final board and change the driver) THEN I will start recking the alignment again . All looked pretty good with the cal signal all close to S9...except 10 MHZ , like I said was really low S2 or 3 i think.
I found a little plastic rod in my sons lego stuff. It fits down into the can nice. Its short, so I glued into a tube used from a can of compressed air. I will carve and file tomorrow and try for fit. where did you find the NOS tools at? Amazon, Ebay? does it have a name or part number?

Thanks porcupine
---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote: Steve, I have the 5 pc version...but I did get a real good deal on an NOS tv alignment set...this had everything I could possibly need, especially some long shafted tools to get to some on the tuning coils...ie..T-4 on the 830 RF board...as this tool is flexible. It was actually rather cheap...$30.00. Gordon's method sounds fine...about heating the tool...I have not used that method...but I trust his judgement,,,he's been at this a lot longer than I have..hihi. I have several different coil slugs that are found on/in the KW hybrids...I use them to "fine tune" my exacto knife approach as the slugs are junk(broken in half)...and I can observe them under my magnified light..remember... use "decaf" coffee...those damn blades are sharp! I am shooting from the hip here...as I don't have a schematic in front of me...but with all else being equal...there maybe some "crud" on the associated band switch contact points...as the "cal signal" I believe is inserted after L-41..(antenna step xfmr) so should eliminate that as a possible problem. What is the difference between the "S" meter readings? They will tend to decrease as the band changes go higher in frequency...but should NOT fall off from say, "S-9" on 20M to "S-3" on 10M I do not want to steer you in the wrong direction...others here have WAY more diagnostic skills than I do...so, I shall reserve my recommendation to what my limited knowledge allows me to do hey Mo.....

No Joe, I dont get a good cal sig on 30. most other bands are close to or at S9, Thats what makes me wonder if its not "something else"

There are two tool sets on amazon..one have 5 pc the other 12 (I think) which one did you get?

thanks

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote: Steve, I have used the "alignment tool set" from "Amazon" that your were talking about in your original post. The thing that you will have to do is take a very sharp knife...say an exacto...and trim back some of the plastic as the end is at times too short to get to the slug, as the shoulder of the tool can hit on the top of the "can." Or, go to a hobby or

craft store and look for a piece of plastic rod that you can "custom" make your own...or a nice piece of dowel stock. I do not know enough about the noise blanker circuit to offer a logical/correct answer. I think that Terry-k9tw, just answered something about a noise blanker a few posts ago. As far as 30m goes...check for proper adjustment of the associated coils first. Can you get a good "cal signal?"

Topic: 45223 Message: 45223

Here's an interesting issue regarding my R-599D/T-599D "Twins". When the R-599D is turned on, sensitivity is as it should be but when I key the T-599D on any band, upon going back to receive, the sensitivity of the R-599D drops-off. Sometimes after awhile, the receiver's gain will creep back to normal. Powering the receiver off and then back on will also restore normal gain too. The AGC voltage feeding the front-end RF board (X44-0020-00) tracks normally. Since I had some 1N60 diodes around, I replaced the protection diodes D1 and D2 in the antenna input circuit. I think my next step could be a "stressed" 3SK22 MOSFET first RF amp. Before I start tearing more into this, has anyone ran into this little issue before with their Twins ?? Receiver gain recovery after transmit ?? My first impression is that there aren't that many "Twins" out there still in the wild. Not as many as the transceivers for sure. After all these years, still a joy to operate and still get great signal reports.

Regards,

Jim L.

I left the tweakier glued to the slug untill i got max signal, then detached it and did the other..then very gently tweeked the first. i didnt remove them. i am hoping they are high enough that they are getting a good bite now on the threads. I have thought about putting a drop of wax down there..but dont want to temp fate. i got my new brass couplers in from Ken. If anything, they are shipping fast now. so now i need to stop at the hardware store and get a long allen wrench. then once the and switch is in, ill put in the new cathode resistors..and hopefully I'll be set for the winter.... cruising the NEW warc bands. LOL

or maybe ill listen to 3 guys talking to a Nazi sub who wants to be taken over by remote control.

Glue trick worked!
---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:
Steve, Were you trying to turn them and they just went to the bottom? It is NOT uncommon for this to happen. I've had it happen to me about 4-5 times on 530/830's There are several methods: one is to use a very small amount of "super glue" on the very tip on the tuning tool, making sure the the tip goes into the slot...and the tool/tip remains vertical. You get glue between the slug and the thin plastic insulation...you are in trouble!! Don rush..let the glue set up for a few minutes...then SLOWLY & CAREFULLY rotate (counter-clockwise as seen from the front) the tool while applying slight up force...see if it comes up. Take your time...you may have to try the glue several times. The second is to unsolder the offending can and you can insert your tuning tool in through the bottom and turn & push up to the the slug up and out. Take notes on the orientation...most will go back in only one way...but why push your luck. I like the second method better...super glue in a coil form scares the @*#$ outta me. Once the offending slug(s) are out you can use a small piece of waxed dental floss between the slug and the inside of the can to take up some slack, and the wax on the floss acts as a lubricant. Do not use any metal tool or tools on or around those tuning cores/slugs...they will get really mad and break...compounding your problem. They also have slots on both ends...so they can be swapped end for end. These are the two most common methods...good luck & GO SLOW

Joe,

The Lego tuning tool works very well. I got 10 MHZ to pop up to an S5 adjusting the rear, then i went to the front coil and it wasnt doing anything. I re re checked to make sure I was on the right coil. but it just stayed at the bottom of the can. I went back to the first coil and without much effort, the slug slipped to the bottom. So now I have two slugs sitting on te bottom of the cans. Is there a way to push them back up? I was concering de solderin them to see if it was open on the bottom, then push them back up to the top. and then resoldering.

any experience with these?

steve

I have the rig apart, now. I am waiting on Kens couples before i power up again. The plastic coupler on the band switch is broke. i was able to tighten up a bit as the screws were loose as well. Then when i was going through it again, i noticed that one of the set screws was now hanging out...by a thread. (haha) so i pulled that screw out, others are loose because the plastic scratched. i dont want to risk having a screw fall out when 900 volts is on. so once that is fixed, i will clean the contacts again (also will swap out the resistors on the final board and change the driver) THEN I will start recking the alignment again . All looked pretty good with the cal signal all close to S9...except 10 MHZ , like I said was really low S2 or 3 i think.
I found a little plastic rod in my sons lego stuff. It fits down into the can nice. Its short, so I glued into a tube used from a can of compressed air. I will carve and file tomorrow and try for fit. where did you find the NOS tools at? Amazon, Ebay? does it have a name or part number?

Thanks porcupine

Steve,   I have the 5 pc version...but I did get a real good deal on an NOS tv alignment set...this had everything I could possibly need, especially some long shafted tools to get to some on the tuning coils...ie..T-4 on the 830 RF board...as this tool is flexible. It was actually rather cheap...$30.00.   Gordon's method sounds fine...about heating the tool...I have not used that method...but I trust his judgement,,,he's been at this a lot longer than I have..hihi. I have several different coil slugs that are found on/in the KW hybrids...I use them to "fine tune" my exacto knife approach as the slugs are junk(broken in half)...and I can observe them under my magnified light..remember... use "decaf" coffee...those damn blades are sharp!   I am shooting from the hip here...as I don't have a schematic in front of me...but with all else being equal...there maybe some "crud" on the associated band switch contact points...as the "cal signal" I believe
is inserted after L-41..(antenna step xfmr) so should eliminate that as a possible problem.
What is the difference between the "S" meter readings? They will tend to decrease as the band changes go higher in frequency...but should NOT fall off from say, "S-9" on 20M to "S-3" on 10M   I do not want to steer you in the wrong direction...others here have WAY more diagnostic skills than I do...so, I shall reserve my recommendation to what my limited

knowledge allows me to do hey Mo.....

No Joe, I dont get a good cal sig on 30. most other bands are close to or at S9, Thats what makes me wonder if its not "something else"

There are two tool sets on amazon..one have 5 pc the other 12 (I think) which one did you get?

thanks

Steve, I have used the "alignment tool set" from "Amazon" that your were talking about in your original post. The thing that you will have to do is take a very sharp knife...say an exacto...and trim back some of the plastic as the end is at times too short to get to the slug, as the shoulder of the tool can hit on the top of the "can." Or, go to a hobby or craft store and look for a piece of plastic rod that you can "custom" make your own...or a nice piece of dowel stock. I do not know enough about the noise blanker circuit to offer a logical/correct answer. I think that Terry-k9tw, just answered something about a noise blanker a few posts ago. As far as 30m goes...check for proper adjustment of the associated coils first. Can you get a good "cal signal?"

Subject: [TS-520_820_530_830] R-599D gain recovery after transmit ...

Here's an interesting issue regarding my R-599D/T-599D "Twins". When the R-599D is turned on, sensitivity is as it should be but when I key the T-599D on any band, upon going back to receive, the sensitivity of the R-599D drops-off. Sometimes after awhile, the receiver's gain will creep back to normal. Powering the receiver off and then back on will also restore normal gain too. The AGC voltage feeding the front-end RF board (X44-0020-00) tracks normally. Since I had some 1N60 diodes around, I replaced the protection diodes D1 and D2 in the antenna input circuit. I think my next step could be a "stressed" 3SK22 MOSFET first RF amp. Before I start tearing more into this, has anyone ran into this little issue before with their Twins ?? Receiver gain recovery after transmit ?? My first impression is that there aren't that many "Twins" out there still in the wild. Not as many as the transceivers for sure. After all these years, still a joy to operate and still get great signal reports.

Regards,

Jim L.

I agree that cleaning relay is good idea.

I dont know what AGC tracks normally means? Does that mean you measured AG2 terminal on RF board at normal receive and immediately after keying and unkeying and you see exact same voltage level?

When receiver gain is normal suggest you measure G1 and G2 of Q1 with hi Z meter (11meg vtvm) and record the values. Meter may pull voltage down.

Key rig and unkey and watch voltage directly at each gate to see if it is lower now and slowly comes back up to the voltage level that provides normal receive sensitivity. Then you know that it is the control voltage/bias on Q1 that is the issue.

If not G1 G2 voltage problem at Q1 then repeat measurements on the IF amp gain controlled devices.

Terry K9TW.

Yep. After I sent this message, I checked further and it IS the T-R relay in the T-599. Now, where did I put that contact burnishing tool. When your dealing with microvolts going through a set of contacts, it doesn't take much to interrupt or reduce the signal path.

Yep. After I sent this message, I checked further and it IS the T-R relay in the T-599. Now, where did I put that contact burnishing tool. When your dealing with microvolts going through a set of contacts, it doesn't take much to interrupt or reduce the signal path.

Here's an interesting issue regarding my R-599D/T-599D "Twins". When the
R-599D is turned on, sensitivity is as it should be but when I key the
T-599D on any band, upon going back to receive, the sensitivity of the
R-599D drops-off. Sometimes after awhile, the receiver's gain will creep
back to normal. Powering the receiver off and then back on will also
restore normal gain too. The AGC voltage feeding the front-end RF board
(X44-0020-00) tracks normally. Since I had some 1N60 diodes around, I
replaced the protection diodes D1 and D2 in the antenna input circuit. I
think my next step could be a "stressed" 3SK22 MOSFET first RF amp.
Before I start tearing more into this, has anyone ran into this little
issue before with their Twins ?? Receiver gain recovery after transmit ??
My first impression is that there aren't that many "Twins" out there
still in the wild. Not as many as the transceivers for sure. After all
these years, still a joy to operate and still get great signal reports.

Regards,

Jim L.

My R-599 had the same problem. I replaced the T/R relay in the T-599, and never had the problem again. If you connect an antenna directly to the R-599's input, and receive is normal you can suspect the relay.

I never use VOX on fone (Actually don't get on fone at all) with my TS520 or TS440s
 BUT the VOX is a useful tool for working "semi" break-in on CW also.
In the CW mode with the VOX turned on you just have to press the key down to switch from Rec to XMIT. The Delay setting can be advanced for more hang time before the receiver comers back on after you stop pressing the key (or slapping the paddle or bug)...

Hi all

This is my first post so firstly thank you for welcoming me to your group. I am a newly licensed ham having gained my UK Foundation class license just 3 or 4 weeks ago.

A club member kindly sorted me out with a Kenwood TS 430S and having read about the hybrids I quickly sourced an 830S also and I am utterly smitten by it.

Secondly, apologies for this being slightly off topic but as part of my research into the vintage KW's I can across a Kenwood Datamitter DR-100 on ebay. It is clearly some kind of data mode interface and was made around 1983/84 but cannot find out any information on it.

Google throws up a couple of very vague Japanese and Chinese sites and Kenwood UK have no details at all on it.

Whilst the mic input / output works fine with the TS430S it needs some modification as there is a port which I assume connects it to a computer and this must somehow trigger a relay to flick it in to transmit mode so if any one happens to have any information on this I would be very grateful to hear it. In particular a manual would be fantastic.

This is a link to a photo of it hosted on my web space -

Yep. After I wrote my post, I went and took another look. Sure enough, the contacts in the T-R relay in the T-599D needed some TLC and after I located my contact burnishing tool, all is well again until the next time. Happens when relay contacts are passing microvolts through them. Doesn't take much to interfere with the signal path.

Regards,

Jim L.

Joe,

I have seen messages, some of mine, have taken quite a while to get posted. This doesn't happen all the times but it does happen. This has occurred not only after Yahoo made the change but it also has occurred before they made the change. I have even seen messages that appear to get "lost" in the "bit bucket" then after a few days, even as long as a week, suddenly appear.

I can't say with any certainty what is causing this, only Yahoo knows. Don't expect a quick response from Yahoo, they are slow to respond. Yahoo took a couple of weeks to respond to my comments about their bad choice for change.

@Gordon - Innards and other photos posted in an album on the photos page. You can see the relay at the bottom of the board near the speaker cut out. I currently have it set up so that the audio out from my soundcard connects to the AF In cable you can see on the back.

The Mic cord is then connected to the Mic in on the TS430S.

I have used MixW to generate a data signal and applied 9V to the relay and it does indeed operate the 430S PTT function and send the data signal in.

So, now I need to figure a way of using perhaps the speaker out (white jumper socket near the relay toward the back of the board) as an AF signal and build a little module accordingly

The advantage then is that I can still have a Mic plugged in and use the TS430S on Phone as well without unplugging everything.

@Terry - Baud rates are 300 / 600. I have found a little more on the system as a whole. It would seem that the Datamitter was used in conjunction with a piece of software Kenwood called 'Letter' and indeed was originally for 2m FM transmissions.

The screenshots of Letter can be seen at
http://www.geocities.jp/upd780c1/n80/list3/ken/index.html
http://www.geocities.jp/upd780c1/n80/list3/ken/index.html (and if you use Chrome google will translate the page) and it shows a TM 401 being used.

Further, if you see the photo here -
http://www.lvye.org/modules/lvyebb/viewtopic.php?view=1&post_id=1055879
http://www.lvye.org/modules/lvyebb/viewtopic.php?view=1&post_id=1055879 - you can see the Datamitter box and it clearly shows it sitting on top of a rig that looks very much like a TM 401.

I will keep playing with it and if anyone comes across any further information on it I would be very grateful of hearing of it.

Ok looks like your research is getting you the needed details. I looked for a manual and came up empty. I thought the baud rate would give you a clue. Many years ago I got involved with FSK, but no recent experience.

Should be lots of folks on forum that can help you.

Surprised I couldnt find a manual or schematic?

Wonder if Kenwood USA has any parts for it? Might be worth a call?

Maybe an interface to get a VHF/UHF transceiver on digital modes?

Hi all

This is my first post so firstly thank you for welcoming me to your group. I am a newly licensed ham having gained my UK Foundation class license just 3 or 4 weeks ago.

A club member kindly sorted me out with a Kenwood TS 430S and having read about the hybrids I quickly sourced an 830S also and I am utterly smitten by it.

Secondly, apologies for this being slightly off topic but as part of my research into the vintage KW's I can across a Kenwood Datamitter DR-100 on ebay. It is clearly some kind of data mode interface and was made around 1983/84 but cannot find out any information on it.

Google throws up a couple of very vague Japanese and Chinese sites and Kenwood UK have no details at all on it.

Whilst the mic input / output works fine with the TS430S it needs some modification as there is a port which I assume connects it to a computer and this must somehow trigger a relay to flick it in to transmit mode so if any one happens to have any information on this I would be very grateful to hear it. In particular a manual would be fantastic.

This is a link to a photo of it hosted on my web space -

Topic: 45251 Message: 45251

Hello- Any R-820 experts lurking here? I recently bought a very nice R-820 receiver. It seems to do OK on all bands except 15 meters, the sensitivity is down considerably.I get a noticeable peak on the preselector on 15 meters. With the receiver connected to an antenna, the calibrator signal reads as follows on S-Meter: 1.9 Mhz = S9+25, 3.9 Mhz= S9+22, 7.3 Mhz=S9+12, 14.3 Mhz=S9+7, 21.3Mhz=S-2, 28.3 Mhz= S-8. I carefully checked it over by unplugging/plugging back in connectors and very carefully cleaning switch contacts (no spray).This is my first experience with the R-820 and I am very excited to be able to use one. I do have the service manual and will be studying up. Thank you, Byron WA5THJ

45252. TS-830: weak receive on 10 meter band

Hello group, i have got a very nice working TS-830 with one flaw: 10 meter receive is very weak. Also signal from marker unit is weak on 10 meter.
Has anyone an idea what's the culprit? Or how to re-align 10 meter band?
Thanks in advance.

So far I have posted messages on qrz.com and eham.net and no one has heard of it. I have dropped an email to Ken K4EAA and he has not heard of it either.

No one at Kenwood UK has any knowledge of it but David G5HY - Area Sales Manager for Kenwood UK is in touch with Japan for me to see if they can find anything.

It is bizarre really as I would have though by now I would have found someone who had at least heard of it before but no.

I have a USB to RS232 lead on the way and I am hoping to use MixW's PTT trigger to trip the relay directly as I cannot get it to trip via the data connection.

OK, it won't be being used exactly as Kenwood intended but hey, isn't that one of the roles of a ham - to modify and hack kit to make it work to their needs?!

Ok looks like your research is getting you the needed details. I looked for a manual and came up empty. I thought the baud rate would give you a clue. Many years ago I got involved with FSK, but no recent experience.

Should be lots of folks on forum that can help you.

Surprised I couldnt find a manual or schematic?

Wonder if Kenwood USA has any parts for it? Might be worth a call?

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

@Gordon - Innards and other photos posted in an album on the photos page. You can see the relay at the bottom of the board near the speaker cut out. I currently have it set up so that the audio out from my soundcard connects to the AF In cable you can see on the back.

The Mic cord is then connected to the Mic in on the TS430S.

I have used MixW to generate a data signal and applied 9V to the relay and it does indeed operate the 430S PTT function and send the data signal in.

So, now I need to figure a way of using perhaps the speaker out (white jumper socket near the relay toward the back of the board) as an AF signal and build a little module accordingly

The advantage then is that I can still have a Mic plugged in and use the TS430S on Phone as well without unplugging everything.

@Terry - Baud rates are 300 / 600. I have found a little more on the system as a whole. It would seem that the Datamitter was used in conjunction with a piece of software Kenwood called 'Letter' and indeed was originally for 2m FM transmissions.

The screenshots of Letter can be seen at
http://www.geocities.jp/upd780c1/n80/list3/ken/index.html
http://www.geocities.jp/upd780c1/n80/list3/ken/index.html (and if you use Chrome google will translate the page) and it shows a TM 401 being used.

Further, if you see the photo here -
http://www.lvye.org/modules/lvyebb/viewtopic.php?view=1&post_id=1055879
http://www.lvye.org/modules/lvyebb/viewtopic.php?view=1&post_id=1055879 - you can see the Datamitter box and it clearly shows it sitting on top of a rig that looks very much like a TM 401.

I will keep playing with it and if anyone comes across any further information on it I would be very grateful of hearing of it.

45255. TS520S NEUTRALIZING problem

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-11 11:36:31 UTC
From: <sw20plus@...>
Topic: 45255 Message: 45255

Hi all,
A cple of month ago I've been given a TS520S. IT was . on the outside in much better cdx than my old TS520SE. But in the PA I found a 6146A together with a 6146B.
So I swapped my old tubes from the SE to theS. No problem.
Aftter that I had to Neutralize it. Took the set to our local club station and tried to to the job with the VTVM. Tuned it for neutralization iaw the manual
But no output at all was noticed on the VTVM. nothing at all. So we guessed that it must be allright and no neutralization was needed.
But 2 days ago after some playing around with the rig and have made a cple of nice QSO's with New York en Hongkong (so it is working !!!)
I noticed that the Ip-dip did NOT coincide with the output-peak.
So in my humble thoughts, the neut. is NOT correct.
I build a simple RF probe like the one KEN K4EAA is mentioning on his website.
But again NO output detectable watsoever.....
Checked the manual againm but I am sure that I'd followed all the rules..
I hope this is recognizable for and that someone can give me a hint.
The set has normal output on all the bands and I receive good reports on CW and on SSB.

You say there is no output. You also said you followed the manual's instruction.

The transmitter has to be tuned for fully output first then the SG switch is set to OFF then the neutralizing steps are performed. A "T" connector at the 50 ohm dummy load will allow you to measure the RF output with an RF probe and a VTVM, or scope, while adjusting the neutralizing capacitor. The amplifier enclosure cover must be in place to perform the adjustments.

Are you using an RF probe with the VTVM? If not then you won't see any indication on the VTVM connected to the rear SO-239 connector. You can also use a scope, a 30Mhz or higher scope will work fine.

Never mix 6146As with 6146Bs.

Mike is correct., don't mix the final tubes and also, you will not see any indication on your VTVM
if you are not using an RF probe, or an o'scope.
You can build a very simple RF probe, cost about $2.00
I made a simple "dummy load" from a PL-259 and 2 100 ohm 1/2watt (non-inductive resistors) in parallel (50ohms). Metal film resistors, etc..will work fine for this purpose.
As Mike stated..tune for max power...according to instructions in "op" or "service manual," SG switch to OFF...make necessary connections of measuring equipment/dummy load...adjust the "neutralization trimmer" capacitor for lowest reading while rig is in "transmit mode"...most likely...you will not get a "zero," just adjust for lowest reading.
DO NOT USE A METAL TOOL FOR THIS!!! There is enough RF energy/voltage here to make YOUR "TIMEX" cease ticking..if you happen to slip and "ground out"
The "trimmer" caps are usually very stiff...so make sure the tool that you are using will not
break under the torque required.

I am not a R820 "expert".

1. Peform coil pack alignment. If not entire alignment at minimum do 21.250 coils L6, L13, and L20. See Step 2.4 Table 10.

If no improvement then:
1. Check VCO level at TP-1 on the RF board. Should be approx 1.0 rms rf volts. If not adjust with T6. Service manual describes VCO adjusment.

Hello- Any R-820 experts lurking here? I recently bought a very nice R-820 receiver. It seems to do OK on all bands except 15 meters, the sensitivity is down considerably.I get a noticeable peak on the preselector on 15 meters. With the receiver connected to an antenna, the calibrator signal reads as follows on S-Meter: 1.9 Mhz = S9+25, 3.9 Mhz= S9+22, 7.3 Mhz=S9+12, 14.3 Mhz=S9+7, 21.3Mhz=S-2, 28.3 Mhz= S-8. I carefully checked it over by unplugging/plugging back in connectors and very carefully cleaning switch contacts (no spray).This is my first experience with the R-820 and I am very excited to be able to use one. I do have the service manual and will be studying up. Thank you, Byron WA5THJ

I wonder if you were using a VTVM which only apparently had an RF probe?
My old Voltohmyst put me crook when I reneutralised my TS 820 the other day.
The AC probe was NOT an RF one after all. So I made a simple diode and
capacitor
probe and fed it into my Digital Voltmeter. Worked fine done according
to the manual!
BUT DON"T use a conductive adjuster and use a strong hard plastic or
ceramic one.
The neut cap is often stiff as has been pointed out and there is 900
volts DC present
as well as RF so you might only try it once!!!

I am used to use a TS-820 with a Shure microphone with satisfactory results. Days ago, while the rig was ON, I connected an MC-50 mike.
All of a sudden the s-meter stopped to deflect aand signals were no longer heard.
Absence of any signal!
Someone have a clue about troubleshooting?

I just checked the neutralising on mine, following on from my post last week about the load tuning capacitor being all up one end - no-one has come back with any suggestions on that; I wonder if either my posts aren't making it to the list or if my problems are so off-the-wall no-one has ever encountered them before?

Here's what I did:

Let the radio warm up thoroughly - about ten minutes on receive with the heaters on
Disconnected the aerial and attached a dummy load with a short pigtail to go from the UHF socket on the radio to the N-type on the load
Loaded it up as per the manual on 28.5MHz, only transmitting in short bursts just in case
Switched the SG switch off (this turns off the Screen Grid supply to the PA valves, hence the name - the gain drops to not a kick in the backside off zero)
Switched to SEND just to prove that there was no deflection on the RF meter (there wasn't) - this proves that the screen grid supply is off
Connected a T-piece between the TX and the load, and attached my 'scope
Switched back to SEND and observed a few mV of RF, which only increased as I adjusted the neutralising capacitor with a specially-made perspex screwdriver fashioned out of a 6mm perspex knitting needle

So, my neutralising was perfectly okay and just where I left it.

When I got my TS-520 the neutralising capacitor was way too stiff to turn with a plastic screwdriver and I twisted the end off a couple of times. To free it up, I removed the lid of the PA cage, checked that the anode voltage was close to zero and clipped an earth lead on to ensure it didn't "float up" as HV capacitors are wont to do, and gently freed off the capacitor with a long metal screwdriver with a bit of heatshrink over it. This won't work for tuning the neutralising because the metal screwdriver will affect the tuning.

Be careful. You won't get a second chance with that HT supply.

Gordon and others,

The SG switch does not remove the screen voltage from the final tubes
nor does it reduce the gain of the final tubes. See my video at the
following link that discusses what the SG Switch's function is and what
each position, ON and OFF, actually does:

http://www.n6wk.com/w5rkl/SG%20Switch/

Hm, I can't open that, and I'm not very good with videos anyway.

I'm going by what I was told on this list a few years ago when I got the radio. Now I actually go to look at the diagram, I see it actually biases the screen grid somewhat negative.

Gordon,

Try this link

http://www.n6wk.com/w5rkl/

Then click on the "SG Switch" link. That should take you to the SG Switch folder where you then click on "Function of the SG Switch.wmv" link.

The SG switch positions do not bias the final tube screens based on the SG switch position. The SG switch "positions" simply determines what the screen voltage "polarity" that is applied to the final tube screens. The SG switch has nothing to do with "biasing" the final tube screens so don't use and/or think it does. You will only confuse yourself and others by using that term/phrase.

Having an understanding of how a Pentode vacuum tube works will also help you understand what is taking place when the SG switch is set to either ON or OFF. The same effect can be accomplished by simply "removing" or, as you initially said, "disconnect" the screen voltage from the final tube's screen. If the screen voltage is "removed", no voltage is applied to the screens, regardless of the polarity, the screen will be "negative" in respects to the cathode and plate, preventing electrons from flowing pass the cathode to the screen and plate. However, KW does not do that, KW uses a switch that causes a change in the final tube's screen voltage "polarity". The SG switch is a SPDT switch in the 520, 530, and 820 transceiver. In the case of the 830, the SG switch is a simple SPST switch that grounds one lead of the Rectifier Unit's Relay, RL1, energizing the relay. The set of "SPDT" RL1 relay terminals controls the final tube screen voltage polarity in the same way as the SPDT SG switch in the 520, 530, and 820 does.

I don't know what you were told on this group about the SG switch but the video shows what the SG switch actually does. I did not shown the 830's Rectifier Unit Relay, RL1, circuit in the video, I said so in the video, but if you review the 830 schematic you will see how the 830's RL1 relay SPDT terminals controls the polarity of the 830 final tube screen voltage just as the SPDT SG switch does in the 520, 530, and 820.

i now have the radio all back together, 15 meters had a lower receive sig then the other bands, and no xmit. all other bands were good 100 watts out. i put the case back together (bottom half). now no transmit on the other the bands. My number one suspect at this point is the band switch. i deox it and worked it several times. if it is the bandswitch, which waffer board effects all bands, i figure there has to be a common point some where.
this is a 530s, where i just replaced the coupler on the band switch..i am pretty sure its indexing right.

thanks

Indeed it goes into transmit but the problem is in RX as it's quite deaf.
I mean, I can hear voices and cw but very weak and the s-meter doesn't
deflect at all (I also tried to switch the AGC from fast to slow to off and
vice-versa, as well the af gain is fully clockwise, but no results).

Gordon:

It is common for people to say that the SG switch "removes" or "turns off" the normal positive screen grid voltage. If they stop with that statement then it is not accurate or complete. What Mike is saying it that it not only "removes" the normal SG voltage, but it "replaces" it with -100vdc. I suppose if you want to be really picky could argue it does remove it for a brief moment as the switch and relay contacts are SPDT that are break before make, but that isnt the point that Mike is trying to make. .

In order to cold neutralize the finals you would have to literally physically remove or determinate the SG voltage and the Anode voltage and that is not safe., We did that in the old boatanchor days. The reason for applying -100 vdc "bias" is because with the rig keyed the cutoff bias has been switched to operating bias on the control grid and if additional "bias" was not applied to the SG the tube would conduct. Cannot just remove the SG voltage. It is easier to apply this "bias" to the screen grid than to mess with operating bias on the control grid that is already being switched from -100vdc cutoff to -55vdc operating bias (Q point or zero signal point to set the Class of operation). .

Normally I dont like to think of the -100vdc as bias voltage as it might confuse people. I like to reserve bias voltage term for the control grid. Keeps things cleaner.

OK inquistive folks might ask then if I am seeing RF output at the SO-239 then removing the SG voltage and replacing it with -100vdc must allow some small amount of plate current to flow. If no plate current how would there be any RF output?

No there is Zero plate current with SG switch off and rig keyed. The finals are cut off. What you are seeing is the feed thru RF from the Driver tube applied to the 6146 control grids and passing thru the inter-electrode capacitance between the control grid and the anode. Look at the 6146B tube data sheet and you will see that Cgp is max of 0.22pf. That is 2/10th of a pico farad. A very small coupling capacitor.

OK then why neutralize on 10 meters? Look at the opposition that a 0.22pf cap presents to 28.5mhz and to 3.7mhz and you will have your answer. This is why Mike and I constantly harp about the importance of good fundamental electronics background.

Capacitive reactance is an inverse relationship to frequency. The higher the frequency the less reactance or AC resistance to the RF current.

.159/FC = .159/28.5mhz x 0.22pf = 25k ohms at 10 meters

.159/FC = .159/3.7mhz x 0.22pf = 196k ohms at 80 meters

So you can see that at 10 meters that Cgp offers lower resistance to RF current being fed back from the 6146 plate circuit to the grid circuit. Anytime you couple signal back from the plate to the control grid at sufficient level the amplifier tube can break into oscillation. We want it to amplify and not oscillate so we neutralize the affects of Cgp.

On the lower bands no reason to neutralize as the reactance of Cgp is too high to result in enough rf feedback for the tube to oscillate.

This is why when you neutralize on 10 meters the plate current dip typically will not precisely occur at maximum RF output on the lower bands. People needless fuss about this. Very difficult to make a broad banded neutralizing circuit. Some neutralize at 21 mhz in an attempt to get it to work somewhat across the bands.

All this means is that max RF output (max efficiency) does not occur at true resonance. Kenwood realized that and knew that dip and load was not the best way to load a Class AB1 SSB transmitter. So they provided us with the RF relative power meter and instructed us to simply load for max indication on the RF meter position without exceeding plate dissipation. Because we have ALC and RF negative feedback not loading to true resonance does not result in significantly less linearity or higher IMD products.

If you are interested you can read up on Tetrodes (beam power tubes as well) and learn that the screen grid not only serves as an electrostatic shield it also is the primary determinate for plate current at a given control grid bias voltage level.

Secondary emission, tetrode kink, positive and negative SG current, SG regulation, SG dissipation, etc is interesting reading that all applies to our hybrids Class AB1 SSB amplifier. Today we have gone to Grounded Grid so folks have forgotten or never knew how a grid driven final works or how to load one. SG current meter is the best but KW didnt spend the money for that. We have the RF voltage meter position.

Think about this for a minute. You have + 900vdc on the Anode and -100vdc on the SG and -55vdc on the control grid and the Anode can not produce any plate current.

This says something about the influence that the SG has on plate current and RF output power.

According to my manual. attach the dummy load and tune the radio for max power output at 28.5mhz. slide the SG switch to off position. Attach the RF multi meter probe across the dummy load. Flip the stand-by switch to send and adjust TC-1 to min. RF output. Should be just a couple of millivolts at the most.

Because we have ALC and RF negative feedback not loading to true resonance does not result in significantly less linearity or higher IMD products.

If you are interested you can read up on Tetrodes (beam power tubes as well) and learn that the screen grid not only serves as an electrostatic shield it also is the primary determinate for plate current at a given control grid bias voltage level.

Secondary emission, tetrode kink, positive and negative SG current, SG regulation, SG dissipation, etc is interesting reading that all applies to our hybrids Class AB1 SSB amplifier. Today we have gone to Grounded Grid so folks have forgotten or never knew how a grid driven final works or how to load one. SG current meter is the best but KW didnt spend the money for that. We have the RF voltage meter position.

Think about this for a minute. You have + 900vdc on the Anode and -100vdc on the SG and -55vdc on the control grid and the Anode can not produce any plate current.

This says something about the influence that the SG has on plate current and RF output power.

Hm, I can't open that, and I'm not very good with videos anyway.

I'm going by what I was told on this list a few years ago when I got the radio. Now I actually go to look at the diagram, I see it actually biases the screen grid somewhat negative.

Terry, if you don't mind, I'll add an additional comment about the
TS-830 SG switch.

I made a video that shows the difference between the TS-520, 530, and
820 SG switch circuit and the TS-830 SG switch circuit and how the
TS-830 SG Switch works.

The following link will take you to the w5rkl folder on Gordon's website:

www.n6wk.com/w5rkl/

Once there, click on the "SG Switch" folder link which will take you to
the SG switch video files. Click on the video file titled "Function of
the TS830 SG Switch.wmv" to view the video.

Gordon:

It is common for people to say that the SG switch "removes" or "turns off" the normal positive screen grid voltage. If they stop with that statement then it is not accurate or complete. What Mike is saying it that it not only "removes" the normal SG voltage, but it "replaces" it with -100vdc. I suppose if you want to be really picky could argue it does remove it for a brief moment as the switch and relay contacts are SPDT that are break before make, but that isnt the point that Mike is trying to make. .

In order to cold neutralize the finals you would have to literally physically remove or determinate the SG voltage and the Anode voltage and that is not safe., We did that in the old boatanchor days. The reason for applying -100 vdc "bias" is because with the rig keyed the cutoff bias has been switched to operating bias on the control grid and if additional "bias" was not applied to the SG the tube would conduct. Cannot just remove the SG voltage. It is easier to apply this "bias" to the screen grid than to mess with operating bias on the control grid that is already being switched from -100vdc cutoff to -55vdc operating bias (Q point or zero signal point to set the Class of operation). .

Normally I dont like to think of the -100vdc as bias voltage as it might confuse people. I like to reserve bias voltage term for the control grid. Keeps things cleaner.

OK inquistive folks might ask then if I am seeing RF output at the SO-239 then removing the SG voltage and replacing it with -100vdc must allow some small amount of plate current to flow. If no plate current how would there be any RF output?

No there is Zero plate current with SG switch off and rig keyed. The finals are cut off. What you are seeing is the feed thru RF from the Driver tube applied to the 6146 control grids and passing thru the inter-electrode capacitance between the control grid and the anode. Look at the 6146B tube data sheet and you will see that Cgp is max of 0.22pf. That is 2/10th of a pico farad. A very small coupling capacitor.

OK then why neutralize on 10 meters? Look at the opposition that a 0.22pf cap presents to 28.5mhz and to 3.7mhz and you will have your answer. This is why Mike and I constantly harp about the importance of good fundamental electronics background.

Capacitive reactance is an inverse relationship to frequency. The higher the frequency the less reactance or AC resistance to the RF current.

.159/FC = .159/28.5mhz x 0.22pf = 25k ohms at 10 meters

.159/FC = .159/3.7mhz x 0.22pf = 196k ohms at 80 meters

So you can see that at 10 meters that Cgp offers lower resistance to RF current being fed back from the 6146 plate circuit to the grid circuit. Anytime you couple signal back from the plate to the control grid at sufficient level the amplifier tube can break into oscillation. We want it to amplify and not oscillate so we neutralize the affects of Cgp.

On the lower bands no reason to neutralize as the reactance of Cgp is too high to result in enough rf feedback for the tube to oscillate.

This is why when you neutralize on 10 meters the plate current dip typically will not precisely occur at maximum RF output on the lower bands. People needless fuss about this. Very difficult to make a broad banded neutralizing circuit. Some neutralize at 21 mhz in an attempt to get it to work somewhat across the bands.

All this means is that max RF output (max efficiency) does not occur at true resonance. Kenwood realized that and knew that dip and load was not the best way to load a Class AB1 SSB transmitter. So they provided us with the RF relative power meter and instructed us to simply load for max indication on the RF meter position without exceeding plate dissipation. Most people cant get their RF probe across the dummy load. Some use a coax Tee and measure off the open Tee. Others including me use couple of 100 ohm 1/2 watt resistors in parallel soldered on a PL-259 that is then screwed on the SO-239 directly at rear of rig. Now measure the rf voltage across this mini-dummy load. This takes out long coax jumper and problem of getting on the dummy load resistor.

You need to add one additional step.

After getting the first null you should adjust the Plate Tune and Plate Load caps to see if you get another peak in rf voltage. Typically will. Then null again with the NC trimmer cap. I would adjust the tank caps one more time to see if you get another peak. Typically will but will be less pronounced this second time.

Not necessary to do this but will get a very good neutralization at 28.5mhz.

A good test is to connect RF millivolt meter across the 6146 control grid circuit and then tune the plate tank circuit thru resonance and see if the RF voltage changes. It should not if neutralization is effective. Dont know anyone who does this.

Lastly. some folks just use another receiver sitting close to the rig and adjust NC trimmer for lowest audio level in the speaker. This works well enough for neutralization and carrier null and side band balance if do not have any test gear.

Mike:

I forgot to mention that depending on what 830 schematic you have the switch and/or relay contacts are drawn wrong. To me "normal operation " is for the SG switch to be shown in the On position which means de-energized. Relays contacts should always be shown on any electrical print with the contacts in the de-energized state.

I have a schematic that shows the SG switch off or to ground position and the relay energized, but the contacts are shown in de-energized state.

This is why when you neutralize on 10 meters the plate current dip typically will not precisely occur at maximum RF output on the lower bands. People needless fuss about this. Very difficult to make a broad banded neutralizing circuit. Some neutralize at 21 mhz in an attempt to get it to work somewhat across the bands.

All this means is that max RF output (max efficiency) does not occur at true resonance. Kenwood realized that and knew that dip and load was not the best way to load a Class AB1 SSB transmitter. So they provided us with the RF relative power meter and instructed us to simply load for max indication on the RF meter position without exceeding plate dissipation. Because we have ALC and RF negative feedback not loading to true resonance does not result in significantly less linearity or higher IMD products.

If you are interested you can read up on Tetrodes (beam power tubes as well) and learn that the screen grid not only serves as an electrostatic shield it also is the primary determinate for plate current at a given control grid bias voltage level.

Secondary emission, tetrode kink, positive and negative SG current, SG regulation, SG dissipation, etc is interesting reading that all applies to our hybrids Class AB1 SSB amplifier. Today we have gone to Grounded Grid so folks have forgotten or never knew how a grid driven final works or how to load one. SG current meter is the best but KW didnt spend

the money for that. We have the RF voltage meter position.

Think about this for a minute. You have + 900vdc on the Anode and -100vdc on the SG and -55vdc on the control grid and the Anode can not produce any plate current.

This says something about the influence that the SG has on plate current and RF output power.

Hm, I can't open that, and I'm not very good with videos anyway.

I'm going by what I was told on this list a few years ago when I got the radio. Now I actually go to look at the diagram, I see it actually biases the screen grid somewhat negative.

Topic: 45280 Message: 45280

I had replaced the bandswitch coupler, the resistors on the finals board and I thought i was good to go. Turns out i was able to only get some drive on some parts of each band. So I went ahead and adjusted the drive coils. They were WAY out. All of them adjusted up except for 15 meters. So I have no drive on 15 meters. I am suspecting the contact on the band switch, or something else in the line.
Any suggestions on this?
I am getting a soild 100 watts out now on 20 meters and getting drive on the other bands as well. i have not yet did a full tune up on all the bands, but its much better than it was before the drive adjustments on the RF board.

Terry,

I have also run into those types of errors shown on schematics so I know what you mean.

As you saw in my video, I put the SG switch in the "Open" or "ON" position which indicates the relay is not energized. The 830 schematic I have is the high resolution copy from Gordon's website. The Rectifier Unit's relay contacts directly above the relay coil in the video are shown in the "de-energized" position (SG switch is set to ON), providing a positive voltage to the final tube screens. Closing the switch circuit completes the relay coil circuit, energizes the relay which pulls the relay contact down, changing the source and polarity of the screen voltage from Positive to Negative.

As long as the tech understands how this circuit works and that KW changed the SPDT slide switch to a relay switch and how the basic circuit works, he/she should have no trouble with it. I suspect KW changed the SG switch circuit in the 830 from a slide switch to a relay switch because of the voltages being switched.

If you look at the center of the IF Unit board, you will find VR1 and VR2 close together.

Look at the 530 service manual, page 14. Rotate the pdf file clockwise "one click". Look to the right of the filters placement and you'll find VR1 and VR2, in the center of the board.

Topic: 45255 Message: 45286

I was referring the folks to Tetrodes to understand a grid driven RF amp and the function of the screen grid. The Screen grid serves the same function whether in a Pentode or a Tetrode. If you want to understand the Screen grid and its effect on plate current my advice stands study a Tetrode.

The 6146 tubes in are rigs are more correctly referred to as Beam Power tubes or Beam Tetrodes as they have the beam forming plates to deal with secondary emission.

Yes adding the Suppressor grid converts the Tetrode to a Pentode if you are counting elements. Lots of arguments about naming convention. Even Eimac and Penta use different terms. I believe Eimac calls there 4-400A a radial beam power tetrode. There was also a patent issue between RCA and Phillips around the Pentode name.

So I suggest that if you want to learn how the Class AB1 SSB linear amps in our KW hybrids work and how to load one you will be better served to search on grid driven Tetrode RF amps.

First home brew RF amp I built used a 6L6. Some refer to it as a beam power pentode and some call it a beam tetrode.

Sorry for the confusion and not properly calling the 6146 tube a beam power tube or a beam power tetrode. I would have never thought to call it a Pentode.

It has to be a very high-impedance meter, hence "VTVM". A good digital multimeter presents a pretty high impedance, but doesn't respond particularly quickly and you'll miss the dip.

The easiest thing is to use an oscilloscope. It doesn't even need to be a particularly high frequency 'scope. If you use a 10MHz instrument it will not read the output voltage particularly accurately at 28.5MHz, but that doesn't matter because you don't need to know what the voltage is, just that you've found the minimum. It will be a few tens of mV at the peak and a few mV at the dip. If it's way, way higher - you need to put the 'scope on something other than 5mV/div - you likely have some sort of fault.

Hello Group,
I have begun a winter project with a TS-511S. I have 2 questions. #1 Can this rig be described as an early model Hybrid subject to discussion on this group? #2 Are there any members with experience on this rig in this group?
I have a lot of work to do to bring this radio back to book spec and I do have the op and service manuals. I have the equipment but what I do not have is any operating or tech experience with it.
I may from time to time have some questions and if this does not fit in this group I will have to keep researching on my own. So have a little pitty on me if I bring it up again. I think this group has a combined knowledge above all others so I am at yall's mercy. (I added that piece of puff to boost your desire to tolerate me, I have read some psych texts)

OK I misread your post. Easy to do.

Just hope folks get the bug and want to learn more about how the KW Hybrid transmitter works. Over the years I built several grid driven tetrode amps. Dont see too many people playing with these beast today.

Most dont realize we have "mini-tetrode" amps under the hoods.We just dont have SG meter, SG shunt regulators, or SG protection circuits that the big boys have.

In my day were no mosfet shunt regulators and no mov or arc tube protection. We used gas tube regulators and perhaps a manual reset current relay in SG lead to trip the supply. In my homebrew amps I liked to have a zero center meter and it was the only game in town for loading the amp.

Of course easier to homebrew back then as hamfesting would produce the power supply and tank circuit parts you needed.

Sorry for my confusion.

Hello Gordon,
Yes it does have sweep tubes,6LQ6's I promise not to overdrive it. I need to work on the power supply before that. It is not collector quality although it is does not show any signs of abuse. HV needs some work, but over all it just shows signs of age. I plan to restore it to original. And keep it in the shack.

To the others who responded, it is rare and info is more rare so we can share what we find.

Ok, I am back with this "problem". I will first admit that my reference radio is the top of the line flagship ICOM IC-761. This thing has a REALLY quiet and sensitive receiver. I LOVE my TS-520. I think it is a better radio for SSB. It is just wonderful to listen to, and I get complements about the transmit audio that I never get with the 761. It is a great armchair radio. However, this weekend I was chasing DX on the high bands, and this white noise problem was annoying enough to have me switch back to my 761 for the DX. I sent an email to a local ham friend to see if he has the CW filter installed so that I can listen to his receiver and compare it to another 520s. The white noise is still there even if I switch to FIX or a non existent EXT. VFO. This noise makes up about 50% of the noise floor on a very quiet band (like 10m when the band is barely open). However, again -- it is generated after the signal passes through the Narrow CW crystal lattice filter, but before the audio stage. It is reduced by decreasing the RF gain, but it is MUCH wider than the skirt of the filter. I am wondering if putting Schottky diodes in the balanced detector circuit might improve things -- or not.

Thoughts, opinions, flames? I might be just expecting too much from this old gal, but hopefully I can listen to someone else's radio before resigning myself to that.

Regards,
Chris Maness

45303. Ladder line with AT-230?

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-14 14:20:56 UTC
From: Craig Roberts
Topic: 44803 Message: 45303

Over the weekend I constructed and erected a 65' doublet antenna fed by 600 ohm ladder line and energized by my TS-830S and TS-530S through at AT-230 antenna tuner.

At first, I employed a DX Engineering 1:1 current balun between the antenna and the tuner through a short (3') coax jumper hooked up to ANT 1 or ANT 2 on the Kenwood tuner. I was not able to achieve an SWR lower than about 3:1 on any band.

Then, I eliminated the balun and attached the ladder line directly to the tuner through the ANT 3 (feedthrough) and ground connections. I am now able to tune the antenna to an SWR reasonably close to 1:1 on most bands 80 - 10 (though 80 meters, as expected, is closer to 2:1).

So, to achieve feedline balance and eliminate (theoretically) feedline radiation, should I use a 4:1, 6:1 or even 9:1 balun instead of the seemingly useless 1:1 device? Or, should I just leave wel enough alone and not use a balun at all?

Does anyone else use ladder line with an AT-230 tuner?

Thanks and 73,

Craig

Many baluns don't perform well in a bad SWR condition. I purposely
did not use a balun in my G5RV/Jr design.

Hooking the ladder line side to a ground upsets the balance for the whole antenna
Connecting a fixed ratio BalUn will not have the right ratio for most of the bands if you band hop.
A 1:1 BalUn Will be lossy where there is a high SWR.
I highly recommend a true balanced input tuner like the (obsolete) Johnson matchbox, or a MFJ974-HB.
 Many other tuners with a balanced input have an internal 4:1 BalUn and this fixed ratio will be lossy at many higher or lower input Z values where the operating freq is not an odd multiple of the resonant (half wave) length of the antenna wires.

My cantennas had a port on the top to measure rf voltage. I found out if you don't use shielded cables for the connection to the voltmeter it is an antenna and there for will transmit. Depending on the meter used, it can transmit as well. The cheaper ones make good antennas.

I am looking for a circuit board for the notch unit used in the TS-530 SP/D.
The unit number is X51-1310-10. I don't suppose that someone would happen to have one hid in a drawer somewhere that you could send me, or a copy of the negative that I could reproduce one?
Even if you had a GOOD picture or scan of the foil side of the board I could make the board from that. You can fax the later to 440-830-2077.
I have all the other parts to build one.
Thank you for your time.
Bill WD8OSJ

Bill,

  In the "service manual" on pg's 53 & 54 shows the "notch" board schematic & x-ray view. They may not suit your needs.

  Try Bob Mansker-ke5ftf at: ke5ftf@...   he has LOTS of good working parts for reasonable prices for most KW hybrids,

I just sent him an e-mail as to my needs.
Yes, I have that manual but the x-ray is very light and hard to see.
If you have a dark x-ray of it please fax it to me and I will see if I can do something with it if Bob doesn't come up with something.
Bill WD8OSJ. God Bless.

Topic: 45310 Message: 45310

Anybody know how to adjust the pointer so that its somewhat close to which band i am operating? It was was off (maybe this means there is another problem) but what I did was dipped for 20 meters. Powered down and loosened the rear coupler, I held the coupler and rotated the pointer to 20m and tightened the coupler back up. Now the pointer is fine for 20m, but not so good for the other bands. I searched the users manual and didnt find this in it.

thanks

steve

Hi Guys, Thanks for letting in the group, I'm Lee, I like running these old radios and working on them. Every now and then I get lucky and get one repaired though mine is getting kind cranky Hi! The carrier control pot wont vary the carrier anymore in cw mode don't know what happened,it just stopped working, the pot seems to be ok. I have 110 watts on ssb with abt 210 ma also the meter function in alc mode stopped working even with advancing the mike gain. You can see a slight meter movement in alc. The alc seams to be doing its job but somethings going on with the metering. All other meter modes work. The alc meter function stopped some time back ,I ran across some info on troubleshooting this circuit but haven't found the problem yet. Thanks Again,Lee

Steve,

In relation to your pointer problem. Has this changed recently? Where did it point on the lower bands before you adjusted it, specifically 1.8, 3.5 and 7.0 Mhz? Don't forget that the pointer may not directly point at the number on the front panel, there are raise painted areas that covers the band, some are small others are larger it should be within the raised painted area. Please advise and we can go from there.

thanks Dave,
I just got this radio about 2 weeks ago. My main rig is a 520. The pointer on that has always been close,but not exact, so i am not expecting to be to close, just nearby would be good I think. Some bands its pointing down. I dont think it ever was close to a band where I was operating...in fact now that i think about it, it wasnt dipping at all when i first put it on the air. It was loose in the coupler so it was just spinning around, not turning the cap at all. So it has no real home and it should be set from scratch.

My Histiory to date with this rig so far: I have replaced the band switch and the load couplers, the cathode and screen resistors and cleaned all the band-switches, neutralized the finals, adjust the drive coils and did a receiver alignment. All on air reports have been very good audio and signal.

thanks

Steve,

The "pointer" position is an approximate indication...NOT exact...as you noticed and stated about your 520.

With the plates of the "air variable" capacitor in the final cage 50% un-meshed (should look like a "pac man" with the mouth facing to the right....the pointer should be "around" the "14"

With the plates fully "un-meshed" the pointer should be at or possibly just past "28"

With the plates "fully meshed"..the pointer should be at/around the start of the arc for 3.5mhz.

Don't over analyze it...it's a guide...and MAY NOT be exact!
If however, that you "load up" and the plates are way off...that may be cause for concern.

Steve let me known if you would like some photos taken and sent to you for setting up the meshing and alignment of pointer. Once the pointer has been realigned then you can check on the tuning for all bands. I have two 530s here, both are within a bee's whisker of each other. I'm thinking about installing the digital hold function on both my 530s, I find it very good when chasing DX

45320. TS-830 SG switch position on the 830 schematics

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-15 14:31:27 UTC
From: Mike
Topic: 45320 Message: 45320

There's an error in the TS-830 schematics that shows the SG switch set to the "OFF" position yet the Rectifier Unit's relay, RL1, it is shown in the "non-energized" state. If the 830 SG switch is in the "OFF" position, as shown in the 830 schematic, the Rectifier Unit relay, RL1, would be "energized" changing the screen voltage from positive to negative. That is not how the Rectifier Unit relay is shown on the 830 schematic with the SG switch shown in the OFF position. My video on the 830 SG switch shows the correct placement of the SG switch in the ON and OFF position and how each position controls the Rectifier Unit relay RL1 and how RL1 controls the "Positive" voltage to the screens (SG ON) and the "Negative" voltage to the screens (SG OFF).

I have found this error to exist on every TS-830 schematic I have downloaded. Therefore, when you are studying/troubleshooting the SG switch circuit, ensure you understand this error exist on the 830 schematics.

Mike,

Terry and I were just discussing this last week. I understand there are some other errors as well with this schematic of the TS-830S. Might want to talk to Terry.
Bill WD8OSJ

---In ts-520_820_530_830@yahoogroups.com, <w5rkl@...> wrote:

There's an error in the TS-830 schematics that shows the SG switch set to the "OFF" position yet the Rectifier Unit's relay, RL1, it is shown in the "non-energized" state. If the 830 SG switch is in the "OFF" position, as shown in the 830 schematic, the Rectifier Unit relay, RL1, would be "energized" changing the screen voltage from positive to negative. That is not how the Rectifier Unit relay is shown on the 830 schematic with the SG switch shown in the OFF position. My video on the 830 SG switch shows the correct placement of the SG switch in the ON and OFF position and how each position controls the Rectifier Unit relay RL1 and how RL1 controls the "Positive" voltage to the screens (SG ON) and the "Negative" voltage to the screens (SG OFF).

I have found this error to exist on every TS-830 schematic I have downloaded. Therefore, when you are studying/troubleshooting the SG switch circuit, ensure you understand this error exist on the 830 schematics.

45323. ts-520 10 meter question general question

Topic: 45323 Message: 45323

First thank you to everyone who has posted both questions and answers, being a new operator I've already learned a lot from previous messages and files. I'm still learning and very green (i'm not the quickest at dipping and peaking yet or even finding all the knobs) but my question is with a 10 meter dipole I have, I read a higher SWR on the 28.5 band switch settings, and much lower SWR's on the 28 band and 29.1 band. If I understand everything I've learned so far, this is opposite of what I would expect. I.e., I should be reading one low SWR somewhere, and increasingly higher SWR's. Since to me it seems inverted of what is should be, what should I be focusing on? Also possibly related if i'm not consistently doing it, is the need to dip and peak when changing "bands" related to the band switch on the radio or just the general ham band, meaning that you only dip and peak once for 10 meter instead of each of the three 10 meter band switch settings.

First, it is good form to sign your posts with your first name and callsign.
You should retune the final slightly when you go form you go from one end of a band to the other. SWR changes when you change frequency away from the antennas resonant point

If the SWR is higher on the low end , it means your longer than optimum, when it is low on the high end it is longer than optimum length.

I also noticed that all the other switches were in the off/stby modes. Could it be that it was customary to show the switches in the off position?
I understand that the SG switch must be on to transmit, but nothing on the schematic shows that it is in rec or trans. In fact looking at the 530 and the 820 they show the SG switch in the off position as well. The 520 shows it in the on position. Just food for thought and my opinion. I know when I was in engineering school, Many Moons ago, we had symbols that were standard practice to use in drafting. This could be the case here.

Bryan,

You need to tune the finals at every frequency you transmit on. If I move more than about 20kHz from where Iast tuned up, I tune up again.

If you tuned your finals at 28MHz then switched bands to 28.5MHz and made an SWR measurement without tuning again the results are likely to be meaningless.

73,

Bill

Bill, I can't speak for Kenwood engineers on whether their use of schematic symbols are, as you referred to them as, "standard practice to use in drafting".

This error appears on all TS-830 schematics I have downloaded/found, including the schematics in the operator and service manuals.

I am sure there are other errors but this post was about the SG switch error only.

Subject: [TS-520_820_530_830] RE: plate knob/pointer adjustment 530s

thanks Dave,

I just got this radio about 2 weeks ago. My main rig is a 520. The pointer on that has always been close,but not exact, so i am not expecting to be to close, just nearby would be good I think. Some bands its pointing down. I dont think it ever was close to a band where I was operating...in fact now that i think about it, it wasnt dipping at all when i first put it on the air. It was loose in the coupler so it was just spinning around, not turning the cap at all. So it has no real home and it should be set from scratch.

My Histiory to date with this rig so far: I have replaced the band switch and the load couplers, the cathode and screen resistors and cleaned all the band-switches, neutralized the finals, adjust the drive coils and did a receiver alignment. All on air reports have been very good audio and signal.

thanks

Steve,

In relation to your pointer problem. Has this changed recently? Where did it point on the lower bands before you adjusted it, specifically 1.8, 3.5 and 7.0 Mhz? Don't forget that the pointer may not directly point at the number on the front panel, there are raise painted areas that covers the band, some are small others are larger it should be within the raised painted area. Please advise and we can go from there.

Subject: [TS-520_820_530_830] plate knob/pointer adjustment 530s

Anybody know how to adjust the pointer so that its somewhat close to which band i am operating? It was was off (maybe this means there is another problem) but what I did was dipped for 20 meters. Powered down and loosened the rear coupler, I held the coupler and rotated the pointer to 20m and tightened the coupler back up. Now the pointer is fine for 20m, but not so good for the other bands. I searched the users manual and didnt find this in it.

thanks

steve

45331. meter peg on power up 530s

Well certainly not radio and electronic industry standard. Perhaps KW standard, but I doubt it. Most transceiver mfg. schematics I am familiar with show the radio in Rx mode with no off air signal applied. All relay contacts in de-energized state. When a radio mfg depicts relay contacts in energized state that is not industry convention and can cause you to chase your tail.

Look at lower right hand legend on the Large Hi Res TS-830 Schematic and you will see the voltage levels noted are for the rig in RX mode 14.175mhz no signal. Yet it shows the mode switch in Tune, the bandswitch at 1.5mhz. Tune wouldnt be a "normal" position for RX mode.

So plenty of apples and oranges depicted on KW schematics.

Just no way to know what KW had in mind and why so many errors in the documentation. Goes way beyond translation.

When what is depicted doesnt make sense have to put on the thinking cap.

The fellows doing wholesale capacitor change out better do that as there are more than one electrolytic filter caps that are installed reverse polarity. Can you assume that the drawings and board silk screening are correct and the as-built is wrong? Better not do that without some circuit analysis. I know the answer for a few of these and suggest you take a hard look at the as-built.

There's an error in the TS-830 schematics that shows the SG switch set to the "OFF" position yet the Rectifier Unit's relay, RL1, it is shown in the "non-energized" state. If the 830 SG switch is in the "OFF" position, as shown in the 830 schematic, the Rectifier Unit relay, RL1, would be "energized" changing the screen voltage from positive to negative. That is not how the Rectifier Unit relay is shown on the 830 schematic with the SG switch shown in the OFF position. My video on the 830 SG switch shows the correct placement of the SG switch in the ON and OFF position and how each position controls the Rectifier Unit relay RL1 and how RL1 controls the "Positive" voltage to the screens (SG ON) and the "Negative" voltage to the screens (SG OFF).

I have found this error to exist on every TS-830 schematic I have downloaded. Therefore, when you are studying/troubleshooting the SG switch circuit, ensure you understand this error exist on the 830 schematics.

Steve,

Will get you the pictures today. In relation to your panel meter pegging (going FSD) on power up, this is very common and usually related to have an antenna connected on power up. I like most others who have experienced this have found that disconnecting the antenna or switching antenna to ground when radio is not in use prevents this problem. I make a habit of prior to connecting radios to patch panel to earth out the antenna, only to find the antenna has a static build up on occasions.

Does anyone know the value of the VFO tuning capacitor in the 520 or 820? Also, the capacitor labeled TC1 on the schematic? I don't want to take my 820 VFO out of the radio just to measure the cap.

I'm thinking about duplicating the VFO circuit for a receiver I'm building and Kenwood doesn't give the value in the parts list. If I knew the value of the tuning inductor I could calculate the capacitor, but they don't give that in the parts list either.

Ill have to try that. I have a loop antenna. I usually just unhook it from the Low Pass Filter when I am out of the shack in case of lighting. But I will try grounding it to see if that helps out next time.

Is this the little trimmer cap, or the actual VFO tuner? For the trimmer 22pF would be a good starting point. Have a look at other similar designs and see what they use.

You should not have to ASSUME anything on any paper work for any Radio. If you want to really get down to it, all the voltage readings are false as well as the signal paths. If you look at the power switch and the heater switch, they are in the OFF position. That means that there is NO way any voltage can be anywhere in the rig.
I have worked on Radios and TVS for most of my life and would never start to work on one without at lease the schematic. All of the SAM Photofacts I have seen over the years for radio and TV ALWAYS show switches in the OFF mode and Relays in the NC position. I don't know what the big deal is over the SG switch is anyway. If you are a Ham or a service man you should that the SG switch needs to be ON to transmit as well as the power and heaters. There are other schematic's of other radios out there that show this SG switch OFF. Why pick on the 830 as the 820 and the 530 also show the SG switch OFF. Look for yourself. Bill WD8OSJ The End For Me.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Well certainly not radio and electronic industry standard. Perhaps KW standard, but I doubt it. Most transceiver mfg. schematics I am familiar with show the radio in Rx mode with no off air signal applied. All relay contacts in de-energized state. When a radio mfg depicts relay contacts in energized state that is not industry convention and can cause you to chase your tail.

Look at lower right hand legend on the Large Hi Res TS-830 Schematic and you will see the voltage levels noted are for the rig in RX mode 14.175mhz no signal. Yet it shows the mode switch in Tune, the bandswitch at 1.5mhz. Tune wouldnt be a "normal" position for RX mode.

So plenty of apples and oranges depicted on KW schematics.

Just no way to know what KW had in mind and why so many errors in the documentation. Goes way beyond translation.

When what is depicted doesnt make sense have to put on the thinking cap.

The fellows doing wholesale capacitor change out better do that as there are more than one electrolytic filter caps that are installed reverse polarity. Can you assume that the drawings and board silk screening are correct and the as-built is wrong? Better not do that without some circuit analysis. I know the answer for a few of these and suggest you take a hard look at the as-built.

The SG switch is a big deal because with it off the contacts cannot be as depicted showing 250 vdc applied to the Screen grids of the finals. It is a big deal as it confuses people trying to troubleshoot a radio. The question is which is correct the relay contacts or the SG switch?

Sadly few would even recognize there was a question unless a student of rig.

If it was such a none issue and it made sense why then did you write me and ask how it worked?

If it confuses an experienced person like you imagine what it does for the new person that doesnt know what a Sams Photofact is..

We are not picking on the TS830. We are simply trying to help people when errors are uncovered in any of the documentation and there is plenty to go around across all the rigs.

I cant wait until you start working on a TS820 and the wrong test point, wrong adjustment trimmer, and wrong acceptance criteria are all called out in the same step. You will need all those years of experience to figure it out. Typically after you have already adjusted the wrong trimmer and messed up another function.

There's an error in the TS-830 schematics that shows the SG switch set to the "OFF" position yet the Rectifier Unit's relay, RL1, it is shown in the "non-energized" state. If the 830 SG switch is in the "OFF" position, as shown in the 830 schematic, the Rectifier Unit relay, RL1, would be "energized" changing the screen voltage from positive to negative. That is not how the Rectifier Unit relay is shown on the 830 schematic with the SG switch shown in the OFF position. My video on the 830 SG switch shows the correct placement of the SG switch in the ON and OFF position and how each position controls the Rectifier Unit relay RL1 and how RL1 controls the "Positive" voltage to the screens (SG ON) and the "Negative" voltage to the screens (SG OFF).

I have found this error to exist on every TS-830 schematic I have downloaded. Therefore, when you are studying/troubleshooting the SG switch circuit, ensure you understand this error exist on the 830 schematics.

Bill:

I am aware of that the other rigs show the SG switch in both positions. I wish they were all depicted in the On or Operational position and not in the Off or Service position, but it is not a major obstacle if you consider normal to be On which would then align with the 6146 screen grid voltages shown and you understand in On there will be approx +250vdc applied to the screen grids.

What makes the TS-830 SG switch different than the others is you cannot look at it in isolation or compare it to an On Off switch. If it was simply an On Off switch it would be easy to debate whether On or Off is the normal position. Hopefully we could agree that On or the operational position would be the normal position. Assumes your rig is configured for operation more than it is for service. I know where my SG switch is at 99.99% of the time. As you say then no big deal.

However, it is not that simple. The SG switch must be looked at in concert with the relay coil that it controls. As drawn they do not align and begs the question which is correct. The switch or the relay contacts? The convention I prefer to see is relays in the de-energized state.

So just annotate your TS-830 schematics to show the SG switch to the ON position and it will align with the relay contacts as shown.

On June 30 of 2011 I brought this issue to this esteemed body along with problems with Gate 1 of Q1 RF amp and was essentially told these schematic errors were old news and that I should check subsequent revisions. I have yet to find those revisions.

Sorry it keeps coming back. I promise you wont hear it from me again. In my zeal to help I sometimes go overboard. Its all Mikes fault for making his SG switch video!

We can debate what is normal convention all day long. Nothing to gain by that.

Point of all of this protracted discussion is I am trying to help new folks who intend to repair and maintain a KW hybrid. They all need a "4 legged" stool. 1. Fundamental electronics and basic understanding of how a SSB transmitter and receiver works 2. Minimum amount of modest test gear and how to use it 3. Accurate rig specific documentation ie instruction manual, service manual, schematics etc 4. Experience.

They cannot get 1 and 4 overnite, but 3 should be relatively easy to get. I know those who have purchased 2 but struggle with how to use it. That hopefully will come with time.

This is why I am a stickler for full and accurate documentation.

Absent any of these 4 and you come to this forum for help.

You should not have to ASSUME anything on any paper work for any Radio. If you want to really get down to it, all the voltage readings are false as well as the signal paths. If you look at the power switch and the heater switch, they are in the OFF position. That means that there is NO way any voltage can be anywhere in the rig.
I have worked on Radios and TVS for most of my life and would never start to work on one without at lease the schematic. All of the SAM Photofacts I have seen over the years for radio and TV ALWAYS show switches in the OFF mode and Relays in the NC position. I don't know what the big deal is over the SG switch is anyway. If you are a Ham or a service man you should that the SG switch needs to be ON to transmit as well as the power and heaters. There are other schematic's of other radios out there that show this SG switch OFF. Why pick on the 830 as the 820 and the 530 also show the SG switch OFF. Look for yourself. Bill WD8OSJ The End For Me.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Well certainly not radio and electronic industry standard. Perhaps KW standard, but I doubt it. Most transceiver mfg. schematics I am familiar with show the radio in Rx mode with no off air signal applied. All relay contacts in de-energized state. When a radio mfg depicts relay contacts in energized state that is not industry convention and can cause you to

chase your tail.

Look at lower right hand legend on the Large Hi Res TS-830 Schematic and you will see the voltage levels noted are for the rig in RX mode 14.175mhz no signal. Yet it shows the mode switch in Tune, the bandswitch at 1.5mhz. Tune wouldnt be a "normal" position for RX mode.

So plenty of apples and oranges depicted on KW schematics.

Just no way to know what KW had in mind and why so many errors in the documentation. Goes way beyond translation.

When what is depicted doesnt make sense have to put on the thinking cap.

The fellows doing wholesale capacitor change out better do that as there are more than one electrolytic filter caps that are installed reverse polarity. Can you assume that the drawings and board silk screening are correct and the as-built is wrong? Better not do that without some circuit analysis. I know the answer for a few of these and suggest you take a hard look at the as-built.

Hello!
I also have one of these. As far as I know there was produced 4 versions of these radios. They were produced in the period from 1972 to about 1975. The versions are: TS-900 with 6LQ6 finals, TS-900D with 6146B finals, TS-900X with one 6146B final QRP version for the japanese market and the TS-900S with the 4X150A final.
My PS-900S power supply is marked 100VAC but runs on 240VAC. I guess it have taps for 240VAC or maybe the transformer is changed. It looks original. My radio is produced in 1974 I think, because the power cable is marked "1974". But I'm not shure about this...
I have not found any service manual for the S-version yet. Mine is dead on 15m and the HV reading don't work, so I would like to have a manual. But it seems impossible I'm afraid...

Good day all,

I am trying to locate anything that I can on the TRIO TS-900S hybrid radio that I operate here as my main radio. This radio is the 300 watt, tetrode, forerunner to the Kenwood TS-900. I have full documentation for the TS-900, and the radios are all but identical (except for the final section.)

The TRIO radio was not sold in the U. S., and perhaps not in Europe either (the power supply transformer came wired standard for 100vac, fortunately has taps for 120vac, but supports no other input voltage.)

I would appreciate anything that you can point me toward.

Incidentally, I have available a Kenwood VFO-900 and a Kenwood PS-900 should anyone need one.

The problem so many engineering companies have is with: Change Control. Having retired from the Engineering environment, it is a PITA. So often, the original engineer is now working on another project and the novice gets the old stuff. Then things don't get updated or copy & pasted, thereby carrying over the old mistake. We put a lot of emphasis on correct documentation where I worked. The engineer had to sign off on all technical documents. Updates were issued. It was very uninteresting work, that had to be done.

Have you looked at the documentation of a new Kenwood MC-60 mic? Kenwood still includes a schematic that has the mic & shield ground switched! Fortunately, they don't make them that way anymore. They must have printed a million copies of that manual & keep using them.

Thanks to this group for noting schematic errors. 73 - Bob

Nuclear power spoiled me. Maintaining design basis douments as you say is not too glamorous for any engineer, but a must. With all the modifications over the years plants can get in trouble if they dont have a rigorous program and adequate stafffing to keep all the documents updated in timely manner. Still possible today to find as-built condition in the plant not matching the latest rev or approved drawings. Now the design engineers earn their keep as it may mean a call to the NRC and bringing the plant down.

Some Nuke plants are their own architect engineering firm and others utilize recognized design firms. In either case as you note it can be a challenge if a good system hasnt been implemented. Cant be one based on the engineer that was on site when they were digging the hole. He has retired or been "right sized" out the door.

NRC wont be very understanding if you tell them that back in the day we used "fat pencils" for design calcs or we lost all the tribal knowledge. Very good way to get them to ask you to hand over the keys. That can be very painful at million dollars a day or more from lost electric power generation and it may even affect your attendance when the new management team comes on board.

I wish we could contact KW engineers and have access to design basis documents. Whenever I call KW East or West I get the same response..."that model no longer supported": For most part I think the design has stood the test of time.

But still wouldnt it be nice to find a garage in Japan full of design basis documents! Hopefully not on the back of stained cocktail napkins! I dont think so. Of course a lot of what they did was a direct copy from Collins and they just solid stated it. Nothing wrong with imitating what works.

If you dont believe that look at the TS-830S Q-multiplier and Bridged Tee Notch Filter in the IF chain. It is an exact copy of the Collins 75A4 receiver circuit down to same values for the Tee inductor and capacitors. Only difference is a 121AX7 for the differential amp and not transistors. I just stumbled across that one day and smiled.

That is not how the Rectifier Unit relay is shown on the 830 schematic with the

SG switch shown in the OFF position. My video on the 830 SG switch shows the correct placement of the SG switch in the ON and OFF position and how each position controls the Rectifier Unit relay RL1 and how RL1 controls the "Positive" voltage to the screens (SG ON) and the "Negative" voltage to the screens (SG OFF).

I have found this error to exist on every TS-830 schematic I have downloaded. Therefore, when you are studying/troubleshooting the SG switch circuit, ensure you understand this error exist on the 830 schematics.

45346. RE: VFO capacitor

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-16 17:59:08 UTC
From: <rcbuckiii@...>
Topic: 45334 Message: 45346

I am referring to the actual VFO tuner cap. My guess is the trimmer is probably in the 20-50pF range. With the side plate off of the VFO, the main cap looks like it may be in the 240pF area. I guess I can start with that value and perform the calculations. I was just hoping someone was aware of the value of the cap. The tuning for the VFO is very linear compared to a typical 5.0-5.5 MHz VFO.

Buying a VFO on Ebay and using it for parts is not the answer. That would cost more than the receiver I am building and the reduction drive assembly is not suitable for my case size. I can duplicate the VFO for less than $20 as I have most of the parts on hand.

>
> I'm thinking about duplicating the VFO circuit for a receiver I'm building and Kenwood doesn't give the value in the parts list. If I knew the value of the tuning inductor I could calculate the capacitor, but they don't give that in the parts list either.

Is this the little trimmer cap, or the actual VFO tuner? For the trimmer 22pF would be a good starting point. Have a look at other similar designs and see what they use.

Hi Ron:

Just curious what makes you think you need a replacement power transformer?

Last I knew you had a smoking R6 resistor that feeds 210A and you had replaced the filter caps.

Did you measure the resistance from 210A terminal post to chassis ground after replacing the filter caps? Should be approx 70k ohms.

I dont understand how bad transformer could cause smoking R6?

I dont know the value but have built a couple of 5mhz VFOs.

I used a very good quality 100pf air variable. I got a surplus one with good bearings and heavy brass plates.

At 100pf you need approx 11uhy tank coil. I have not had good luck using toroids as some designs recommend. I used a 5/8 inch ceramic form and wound approx 32 turns of #28 magnet wire. I did not use slug tuned core just air core. I coated windings with home made Q dope by melting styrofoam packing peanuts in acetone. I would not use a phenolic form.

For trimmer cap I would not use a compression trimmer. I used glass piston trimmers. One of the hardest things to find today are good selection of NPO, N and P temp compensating capacitors. You will need them for drift compensation. Use to find them at hamfest, but eBay is about best source now.

Today cheaper to build a DDS VFO unless you have a good junk box. Mike W5RKL has recent experience with this.

Here is very good article on building LC type VFOs

http://www.qrparci.org/wa0itp/chap10.pdf http://www.qrparci.org/wa0itp/chap10.pdf

45351. Kenwood Net Update (November 13, 2013)

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-17 02:05:43 UTC
From: Mark Gilger
Topic: 45351 Message: 45351

There was no net Saturday. Both myself and Jimmy had other commitments.

The Sunday□s 20 meter net had 25 stations
checking in under excellent band conditions. Out of those, there was:

3 running TS-520(x)
0 running TS-530(x)
4 running TS-820(x)
3 running TS-830S

I was running my TS-820. It was the first time
I□ve run the 820 on the net and I think the first
time it□s ever been on 20 meters.

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 □ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins

November 2012, Saturday□s, net total = 47, Sundays total = 20
December 2012, Saturday□s, net total = 74, Sunday□s total = 70
January 2013, Saturday□s, net total = 93, Sunday□s total = 87

February 2013, Saturday□s net total = 103, Sundays total = 87
March 2013, Saturday□s, net total = 112, Sunday□s total =39
April 2013, Saturday□s net total = 52, Sunday□s total = 29
May 2013, Saturday□s net total = 45, Sunday□s total = 50
June 2013, Saturday□s net total = 30, Sunday□s total = 27
July 2013, Saturday□s net total = 63, Sunday□s total = 41
August 2013, Saturday□s net total = 82, Sunday□s total = 50
September 2013, Saturday□s net total = 66, Sunday□s total = 54
October 2013, Saturday□s net total = 25, Sunday□s total = 35 (Month to date)

Net Info:
Saturday: 7.235 @ 3:30 Eastern following the Swan Tech Net
Sunday: 14.316 @ 1800 UTC following the ICOM net

Ron: To tag on to your phone call last evening as I am not sure if you take notes or not.

1. Can leave 210 secondary of transformer disconnected temporarily.
2. Since R6 is literally showing color measure the resistance cold to ensure it remains at 470 ohms and check forward and reverse resistance on new Diode D6 to ensure it is not shorted.
3. If you have to replace either carefully inspect the board to ensure no carbon track at the 210A output terminal post
4. Measure resistance at 210A post to chassis ground to confirm approx 70k ohms (it is most likely a very low value) and if low value remove the top lead from the post. Measure that lead and the post to ground to see if fault is on one or both leads. Should be an orange and yellow lead wire wrapped on the post. Do not try to reuse the wire wraps as they have work hardened and will fracture. Will have to skin back to fresh tinned lead and solder to the post when ready to restore.
5. Look at schematic and determine what likely contributors would be. You will see several voltage dividers including 100k resistors that feed for Side Tone osc, 56k resistors that feed Tune function, R70/R71 on the RF board for Driver tube SG, and the feed to the 6146 tube socket for the screen grids. This includes a series choke, 100 ohm grid stopper resistors, SG bypass capacitors, and possible but not likely carbon track from SG pin across the phenolic socket. I understand you replaced the 6146 finals so not likely internal short inside a tube. Have never seen a shorted SG bypass cap, but again possible. Have seen on phenolic tube socket carbon path.
6. Lastly it could be a pinched lead but not likely. Also, I have seen the foil side of the RF board at R70/R71 have a pretty bad carbon path. Save this for last.

A reminder.The markings on the terminal post of the Rect Board are not voltage levels. They are labels for the various power supplies and the busses or rails they feed. So 210 at the secondary of the transformer is not a voltage. As we discussed the DC voltage of a lightly loaded 1/2 wave rectifier with capacitor filter will be the peak of the AC. 260vdc/1.414 = 184 vac. So when you determ the transformer secondary you cannot expect to measure 210vac it will be something close to 184vac depending on line voltage.

Same for the 800 terminal. If you determ it you will measure approx 330vac and not 800vac. The HV supply is a doubler. 925vdc/2.828 = 327vac.

Report back the resistance values that you read from the yellow and orange wires to chassis ground. Hopefully the fault will appear on just one leg.

Last think make sure that 210 and 300 are not jumpered. This is common hot rod mod. If it is you must remove. If it is then the 300 filter caps could be the problem.

If you dont mind respond back here with resistance readings so other 520 owners who are following this thread can learn from your troubleshooting.

OK lets work on the yellow wire first. It is a very short run from the 210A wire wrap post to a phenolic terminal strip. Not likely it is shorted to the chassis.

It goes from the HV rect board to a 5 terminal phenolic terminal strip near 6146 tube socket. Should see two 110k resistors mounted on the strip. This divides the SG voltage in half to supply the STB terminal on the Audio board. The STB voltage leaves the terminal strip on a brown wire. (just be careful and not trust these colors that I am giving you. I am pretty confident these are correct but you need to confirm for your radio).

Take a good look at the two 100k resistors. Even if they do not look overheated and discolored you need to measure both of them. If one is bad replace both. Look at the terminal strip to make sure no carbon path.

If they are good then you have to go to the AF board and lift the STB lead and see if the 198 ohms to chassis ground is cleared. If it is this means the brown wire isnt pinched and the fault is on the Audio board.

If you still read 198 ohms go back and look at the yellow wire to see if it is pinched or insulation cut. Then you can lift the brown wire off the phenolic terminal strip and measure it. It should read infinite. If not it is cut or pinched and you will have to trace it to the Audio board and inspect its length.

I am not sure what the resistance to ground is for the Orange wire. I need to look at that but for now lets assume at 100k that it is OK.

Report back.

Ron:

I think you are saying that the Yellow lead from 210A to the phenolic terminal strip and the two 100k ohm divider resistors are good and no carbon path to ground at the terminal strip and you are on to lifting the Brown lead off the STB terminal at the AF board? Is this correct?

Let us know if lifting the Brown wire off STB clears the 198 ohms to chassis ground when reading from the lifted Yellow wire at the Rect board 210A post. Should now have approx 175k ohm to ground.

I would not understand how lifting STB off the AF board could clear a 198 ohm fault as the path on the board has a 1 meg resistor one way and a 470k the other and there is no real current in this part to the Side Tone Osc circuit to cause them to fail.

When I look at the STB circuit I would expect that the Yellow wire lifted at 210A should read approx 175k ohm.

When I look at the Orange wire I see approx 120k to ground.

I dont have these values logged, but I do have 210A to ground logged in my notes more than once and it should be approx 71k ohms.

I think you said that Orange reads approx 110k to ground so that is close and probably indicates no problem with the divider resistors and loads on that bus.

I will look at STB some more but it is just not jumping out at me how it is possible to read 198 ohms to ground on STB.

Terry .

OK lets work on the yellow wire first. It is a very short run from the 210A wire wrap post to a phenolic terminal strip. Not likely it is shorted to the chassis.

It goes from the HV rect board to a 5 terminal phenolic terminal strip near 6146 tube socket. Should see two 110k resistors mounted on the strip. This divides the SG voltage in half to supply the STB terminal on the Audio board. The STB voltage leaves the terminal strip on a brown wire. (just be careful and not trust these colors that I am giving you. I am pretty confident these are correct but you need to confirm for your radio).

Take a good look at the two 100k resistors. Even if they do not look overheated and discolored you need to measure both of them. If one is bad replace both. Look at the terminal strip to make sure no carbon path.

If they are good then you have to go to the AF board and lift the STB lead and see if the 198 ohms to chassis ground is cleared. If it is this means the brown wire isnt pinched and the fault is on the Audio board.

If you still read 198 ohms go back and look at the yellow wire to see if it is pinched or insulation cut. Then you can lift the brown wire off the phenolic terminal strip and measure it. It should read infinite. If not it is cut or pinched and you will have to trace it to the Audio board and inspect its length.

I am not sure what the resistance to ground is for the Orange wire. I need to look at that but for now lets assume at 100k that it is OK.

Report back.

Hi Mike:

I have no objection if you follow this thread and help keep me straight.

I did back of envelope calcs on R6 current and if 198 ohms is actual value to ground then we have 470 + 198 limiting the current or 668 ohms. If we assume a 210A voltage of 260vdc then 260/668 = .389 or 390 ma of current. I suspect not this high as the voltage of 1/2 wave rectifier with capacitor filter will pull down with this level of load current. So if we assume 210vdc then 210/668 = .314 or 314ma. P= I squared R or P = .314 x .314 x 470 = 46 watts.

Pretty easy to see why R6 470 ohm 2 watt resistor is smoking dissipating nearly 50 watts.

This small dose of Ohms law is the piece I left out of my response to Ron. I know he would be disappointed if he didnt get his daily dose of fundamentals from me. I have also encouraged him to buy a 1970s ARRL handbook. Beating the same old dead horse.

I recently had a fellow ask me a question off list and he told me if I wanted to give a brief explanation along with the answer he guessed it would be OK. I thanked him for giving me permission to put some Castor Oil in his orange juice! It was not Ron.

I trust you will check the calcs. Always easy to make an error when you start typing calcs.in a response. Of course I am not there with eyes on this rig so have to make assumptions rather than measurements.

Thanks
Terry K9TW

Ron:

I applaud your efforts but not quite correct. Really no need dwell on this much longer other than to understand a little more how transformers and dc power supplies work.

189vac is not the "actual" value. It is the open circuit voltage of the secondary winding of the transformer. You will never see 189vac in operation other than when in the determed state. All transformers have voltage sag when load is applied. I mentioned in my calc that you cannot use 265vdc to determine that wattage that R6 must dissipate.

I also told you that a 1/2 wave power supply with a CRC (Pi) filter will have a dc output voltage of 1.4 x sec vac (189v) only when it is very lightly loaded. The SG supply is not a regulated supply. So you will only see 265vdc in RX mode when there is approx 5ma of load current. Any additional current and the voltage will drop.

Look at your manuals/schematics and you will see SG voltage listed for RX and TX modes as:
TS520 RX = 246 and TX = 208
TS520S RX = 258 and TX = 231 (I question this as being accurate)
TS820 RX = 255 and TX = 210
TS830 RX = 264 and TX = 222

189vac is only there with no load on the winding. The secondary winding of a transformer has resistance and leakage reactance or impedance (Z). Too much typing to explain and calc here. This impedance is sometimes referred to as equivalent secondary resistance or ESR. When load is applied this "resistance" causes IR drop. You wont have 189vac secondary voltage under full load.

What is normal SG load in TX mode?

It is 70k ohm plus screen grid current contribution from the 6146 tubes and the 12BY7A tube. In RX mode normal load will be approx 265/70k = 4ma . In TX normal load will be that 4ma + 12BY7A 5ma + 6146 20 ma = approx 29 ma SG current. So call it 30 ma SG current key down at 100 watts. With Yellow and Orange wires lifted you could get your dc ma meter in series and measure it when you get the fault cleared.

There are two places that you will see voltage drop. 1. Xfmr secondary sag due to ESR and 2. The IR drop across R6.

E= IR or E = 30ma x 470 ohms = 14vdc being dropped across R6 at full load. This means R6 sees approx 14 x 30ma or approx 0.4 watts. So a 2 watt R6 has adequate margin and should never overheat.

With 30 ma load the 265vdc is reduced approx 40vdc because of 14vdc across R6 and 26/1.4= 18.6 vac across xfmr ESR. So in TX mode the 189vac will be approx 170vac.

That 30 ma of normal full load current pulls the 265vdc down as you see above for each rig. A 40 volt drop is normal.

If 30 ma SG load pulls the voltage down 40 plus volts where do you think the voltage goes with 10X or 300ma of short circuit current ?

I was being optimistic when I used 210vdc for the wattage calc.

You could put an analog meter on 210A with this 198 ohm fault on it and power the rig on and quickly read the voltage and down power before R6 begins to smoke. I submit it will be very low.

When you get the rig fixed you can load to 100 watts out and carefully measure 210A ac input and dc output voltages to see the effect of load on the Yellow and Orange busses.

The above are rough calcs to give you an idea of how it works so dont give me an F on my report card if you measure the IR drop across good R6 and find it to be 12vdc and not 14vdc! I am trying to help you understand how SG power supply works.

One take away for you is that I suggest that you make it a practice when repairing these rigs to take measurements and take good notes on as many normal operating voltages and currents as you can. If you develop this practice it will greatly aid you with any future troubleshooting.

Keep us posted on your progress and dont get careless as you have 900vdc in close proximity to where you are working.

Terry and Ron,

Terry, your calcs are correct.

This example shows the importance in the use of Ohms Law in
troubleshooting an actual hybrid problem. This example should also be a
"wake up call" to some group members who are servicing their KW hybrids
that clearly indicates that it is NOT a waste of time learning Ohms Law!!!

I'll continue following along the thread. I would suggest leaving the
entire thread intact so it shows progress that others can "read and study".

45367. Freq. Counter on High Tension Test Points?

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-18 16:26:48 UTC

Topic: 45367 Message: 45367

I have a general question pertaining to working on tube gear. I am working on a DX-40 that is giving me fits. Is it safe to use a Oscilloscope probe with a frequency counter? I am thinking of using my probe to make sure the CG is receiving the correct frequency and not an overtone. I was thinking +70V should be ok into the freq. counter if I use the 10X (or 100X I can't remember) selector in the scope probe. I would tape it the 10X position to make sure it stays that way. What do you guys think?

Thanks,
Chris KQ6UP

Ron,

I don't want to take away any of what Terry is telling you. However, once you have solved and fixed your problem, with Terry's help, may I suggest taking some time and watch the 3 videos I made using Ohms Law with series, parallel, and series parallel resistor circuits. Use the following link:

www.n6wk.com/w5rkl/

Once there, click on the "Basic ohms law" folder then select the desired video. I recommend starting with the series resistors video first, then the parallel resistors video, then finally parallel series resistors video.

I recommend you draw the circuits shown in the video and use a calculator to perform the math calculations so you get some practice. You can change resistor values then repeat the math calculations so you see how the current, resistance, and voltage changes. This is how you learn by doing it yourself.

Trying to make room in my shack/workshop. I have what Iam pretty sure is the top and bottom covers for a ts820. Im thinking of selling each for $5 plus postage. I have pictures. I tried them on ebay but no luck. Im in Canada here. They are in not bad condition with no major scratches ect. ..email me via my private email which is easy enough to find on the web. Just do a web search for VE3AB and my web site will come up and get my email from there. tnx es 73 earl ..PS..I have a TS780 2m/440 rig that Ihave parted out partially as well..if anyone needs some circuit board or maybe the covers.

Chris,

I have used a 10X scope probe with my freq counter. You should look at the specs on your freq counter's input and see what is the max voltage it can take. My counter has a 1M input but can only take a signal of 5Vrms max. If I'm not looking at digital logic I measure the signal amplitude with my scope first with the 10X probe.

Something else you could try is wrapping a few turns of wire around the lead going to the control grid. I haven't tried this on a CG but I have done this with the coil on a grid dip meter to measure its freq and it worked very well.

Another thought is that if you are concerned with an overtone, you don't need to use the counter at all. Just measure the signal with a scope. Measure the time between one cycle. The freq is the reciprocal of the period. You don't need freq counter precision as a 2X overtone will be 1/2 the correct period, a 3X overtone 1/3, etc.

73,

Bill

Yes, thanks Bill. I was thinking about using a scope. It would be safer
at least. F=1/T where T=the number of divsions x time/div.

Thanks,

You might also consider using a loop pickup device so you would not have
to be concerned with a direct contact with the high voltage that might
be in that area!

I just ended up using a scope since I only needed ballpark figures. It worked really well, and the P2P voltages would have been 15V which is too much for the counter.

Thanks,
Chris KQ6UP

45375. TS-820 strange transmit problem

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-19 02:49:21 UTC

Topic: 45375 Message: 45375

I have a Kenwood TS-820S. Receive is working fine. Strange transmit problem.

When the Mode switch is the Tune, CW, USB, or LSB postion and I operate the Send switch I get no plate current and no output. When the switch is in the FSK position, I get almost normal plate current and can tune the rig to about 3/4 full power out. I can only get the load and plate controls to 160 ma into my dummy load with carrier control at max. Maybe a bad 12BY7 preventing full power out.

The other strange thing is when the meter switch is in the RF position, I can only increase the carrier control to about 70 ma plate current before the meter pegs when in FSK mode.

My 50 watt dummy load doesn't have a power indicator but I know the transmitter is putting out decent power in FSK mode as the resistors in the dummy load are getting warm.

Voltages (SG, Plate, Bias) are all normal. They drop about 10% when switching from receive to transmit mode. This drop happens in all postions of the mode switch, not just the FSK mode.

This makes no sense as in most cases the Tune and CW contacts of S6 are tied together. And S6-2 ties Tune, CW, and FSK together. Has anyone seen this issue before or give me an idea where to look for the problem?

Ray,
AB7HE

1. In LSB/USB should be 60ma resting plate current when you flip to send or key the mic. No indication on RF meter position until you modulate the rig (speak in mic). Can you see and adjust the resting plate current in SSB mode?

2. In Tune/CW will be plate current when you have RF drive (Car Pot advanced) only if you have RF drive as indicated by peaking the ALC indication with the Drive control.

Are you certain that Aux and TR relays are keying when you flip to send or key the mic? Sounds like they are based on seeing tube voltage dropping. Bias voltage at Finals control grid better not be dropping only 10%. It should change from approx -100vdc cutoff bias to approx -55vdc operating bias. If not then plate current and no RF output.

3. You can try a new 12BY7A as easy to do, but your rig has the diagnostic meter you need. Turn off SG switch and place rig in CW mode and peak the ALC indication by advancing the Car pot. Should be able to get full scale meter deflection (FSD) and hold there a few seconds on each band without the ALC indication falling off. Should get FSD with Car Pot advanced no more than approx 1000 to 1100. Rest between each band test as Driver tube is running class A (full plate current).

4 If RF detector is pegging at 70ma plate current then turn down the sensitivity pot. You always have to adjust the sensitivity pot. Set it for approx 2/3 deflection at 100 watts out. Would have been handy if KW would have put the pot on the front panel. They provided this meter position as it is better to load a Class AB1 linear amp by tuning for max rf output without exceeding plate dissipation than using the old dip and load method. They also provided it as external wattmeters were not common and they wanted the radio to be instrumented to be stand alone.

5. I would not use a 50 watt dummy load. If you must then have to realize all dummy loads have a duty cycle. Can use it but have to limit key down time.

6. When you get a couple of bucks ahead suggest you get an external wattmeter. Makes a good Loading aid and a good diagnostic tool. Drake W4, Heath HM-102, any of the MFJs are good and give you a SWR bridge and Wattmeter in one piece of test gear. Having actual output wattage tells you a lot more than looking at relative RF output power by measuring rf voltage at SO-239 or measuring the temperature of your dummy load.

Ray, AB7HE,
My TS-830 is a bugger to get going on 14MHz
because the Band Select switch contacts are fussy.
I am suggesting that there may be other contacts involved in your problem.
Can you use an insulated probe to touch/jar the contacts ?

I only use mine at 3 to 5 W EPO,
so don't have any worries about burning anything.

Glen, KK4LPG.

Topic: 45375 Message: 45378

Terry,

Thanks for the comments.

1) I have 60 ma of current when I flip Send switch in CW, USB, and LSB modes. I don't have a microphone as I only operated CW back when I was on the air. I have a 1KHz tone generator and connected it to the microphone input. When I do this and increase MIC control in both USB and LSB I am able to drive plate current to the same 160 ma (on 20 meters) that I get in the FSK mode. So it appears CW is the only mode that isn't functioning.

2) I tuned the rig to the max power out (IP 160 ma) into the dummy load in the FSK position. I then switch to CW mode but the IP stays at 60 ma. This is with the CAR control at max (10 mark). Bias voltage drops from -100 to -63 volts when I flip Send switch in CW mode.

3) In the FSK mode I get almost FSD with CAR control at max on 20 meters in the ALC position. I am only 2 tick marks away from FSD. On 80, 40, and 160 I am able to get FSD at lower levels of the CAR control. However, when I turn SG back on and tune, the plate dip is in the wrong position for 40 and 160. For both of those bands max dip is at the very low end of 3.5 dial marking. On 20, 15, and 10 the dip is in the correct position. On 10 I am only able to get 80 ma of plate current at min dip with CAR at max. This does indicate the 12BY7 is bad. I think I have a spare one somewhere around here - just have to look. When I switch to USB or LSB I am able to get the same levels of ALC deflection as FSK when I inject the 1 KHz. However, in CW mode I do not get any ALC meter deflection.

4) I will perform this step once the rig is working.

5) I am using the dummy load because I have a 40 meter dipole 8 feet off the ground (HOA) as my only antenna and not sure of the impedance it reflects. I have a Heath HM-15 SWR bridge but it doesn't have a watts reading. I just received an order from Mouser yesterday with the parts to build the dummy load that is on the K4EAA website. I am including the power measurement components so I will be able to know what my power out is. Once I am back on the air I will obtain an inline watt meter.

6) I haven't been on the air in 17 years and am wanting to get back on since I will be retiring in Jan and moving to somewhere that doesn't have a HOA. I have a HW-100 and a FT-101E that have sat in the garage for the last 17 years. I built the HW-100 back in 1968 and last used it in 1986. The FT-101 was working and I was using it on a daily basis when I went QRT at the end 1996. I bought this TS-820 10 years ago but have never used it. It has sat in the closet in my office since I bought it. I figured I would try to get it working first as it hasn't been exposed to extreme temperatures. I would be scared to power the other two up without replacing all the power supply caps first. My garage never drops below 100 four months out of the year.

Ray

1. In LSB/USB should be 60ma resting plate current when you flip to send or key the mic. No indication on RF meter position until you modulate the rig (speak in mic). Can you see and adjust the resting plate current in SSB mode?

2. In Tune/CW will be plate current when you have RF drive (Car Pot advanced) only if you have RF drive as indicated by peaking the ALC indication with the Drive control.

Are you certain that Aux and TR relays are keying when you flip to send or key the mic? Sounds like they are based on seeing tube voltage dropping. Bias voltage at Finals control grid better not be dropping only 10%. It should change from approx -100vdc cutoff bias to approx -55vdc operating bias. If not then plate current and no RF output.

3. You can try a new 12BY7A as easy to do, but your rig has the diagnostic meter you need. Turn off SG switch and place rig in CW mode and peak the ALC indication by advancing the Car pot. Should be able to get full scale meter deflection (FSD) and hold there a few seconds on each band without the ALC indication falling off. Should get FSD with Car Pot advanced no more than approx 1000 to 1100. Rest between each band test as Driver tube is running class A (full plate current).

4 If RF detector is pegging at 70ma plate current then turn down the sensitivity pot. You always have to adjust the sensitivity pot. Set it for approx 2/3 deflection at 100 watts out. Would have been handy if KW would have put the pot on the front panel. They provided this meter position as it is better to load a Class AB1 linear amp by tuning for max rf output without exceeding plate dissipation than using the old dip and load method. They also provided it as external wattmeters were not common and they wanted the radio to be instrumented to be stand alone.

5. I would not use a 50 watt dummy load. If you must then have to realize all dummy loads have a duty cycle. Can use it but have to limit key down time.

6. When you get a couple of bucks ahead suggest you get an external wattmeter. Makes a good Loading aid and a good diagnostic tool. Drake W4, Heath HM-102, any of the MFJs are good and give you a SWR bridge and Wattmeter in one piece of test gear. Having actual output wattage tells you a lot more than looking at relative RF output power by measuring rf voltage at SO-239 or measuring the temperature of your dummy load.

I have a Kenwood TS-820S. Receive is working fine. Strange transmit problem.

When the Mode switch is the Tune, CW, USB, or LSB postion and I operate the Send switch I get no plate current and no output. When the switch is in the FSK position, I get almost normal plate current and can tune the rig to about 3/4 full power out. I can only get the load and plate controls to 160 ma into my dummy load with carrier control at max. Maybe a bad 12BY7 preventing full power out.

The other strange thing is when the meter switch is in the RF position, I can only increase the carrier control to about 70 ma plate current before the meter pegs when in FSK mode.

My 50 watt dummy load doesn't have a power indicator but I know the transmitter is putting out decent power in FSK mode as the resistors in the dummy load are getting warm.

Voltages (SG, Plate, Bias) are all normal. They drop about 10% when switching from receive to transmit mode. This drop happens in all postions of the mode switch, not just the FSK mode.

This makes no sense as in most cases the Tune and CW contacts of S6 are tied together. And S6-2 ties Tune, CW, and FSK together. Has anyone seen this issue before or give me an idea where to look for the problem?

Terry,

Thanks for the comments.

1) I have 60 ma of current when I flip Send switch in CW, USB, and LSB modes. I don't have a microphone as I only operated CW back when I was on the air. I have a 1KHz tone generator and connected it to the microphone input. When I do this and increase MIC control in both USB and LSB I am able to drive plate current to the same 160 ma (on 20 meters) that I get in the FSK mode. So it appears CW is the only mode that isn't functioning.

2) I tuned the rig to the max power out (IP 160 ma) into the dummy load in the FSK position. I then switch to CW mode but the IP stays at 60 ma. This is with the CAR control at max (10 mark). Bias voltage drops from -100 to -63 volts when I flip Send switch in CW mode.

3) In the FSK mode I get almost FSD with CAR control at max on 20 meters in the ALC position. I am only 2 tick marks away from FSD. On 80, 40, and 160 I am able to get FSD at lower levels of the CAR control. However, when I turn SG back on and tune, the plate dip is in the wrong position for 40 and 160. For both of those bands max dip is at the very low end of 3.5 dial marking. On 20, 15, and 10 the dip is in the correct position. On 10 I am only able to get 80 ma of plate current at min dip with CAR at max. This does indicate the 12BY7 is bad. I think I have a spare one somewhere around here - just have to look. When I switch to USB or LSB I am able to get the same levels of ALC deflection as FSK when I inject the 1 KHz. However, in CW mode I do not get any ALC meter deflection.

4) I will perform this step once the rig is working.

5) I am using the dummy load because I have a 40 meter dipole 8 feet off the ground (HOA) as my only antenna and not sure of the impedance it reflects. I have a Heath HM-15 SWR bridge but it doesn't have a watts reading. I just received an order from Mouser yesterday with the parts to build the dummy load that is on the K4EAA website. I am including the power measurement components so I will be able to know what my power out is. Once I am back on the air I will obtain an inline watt meter.

6) I haven't been on the air in 17 years and am wanting to get back on since I will be retiring in Jan and moving to somewhere that doesn't have a HOA. I have a HW-100 and a FT-101E that have sat in the garage for the last 17 years. I built the HW-100 back in 1968 and last used it in 1986. The FT-101 was working and I was using it on a daily basis when I went QRT at the end 1996. I bought this TS-820 10 years ago but have never used it. It has sat in the closet in my office since I bought it. I figured I would try to get it working first as it hasn't been exposed to extreme temperatures. I would be scared to power the other two up without replacing all the power supply caps first. My garage never drops below 100 four months out of the year.

OK well that would have been a quick fix and not first time so had to ask.

What test gear do you have and what is your comfort level to take measurements inside the rig?

When you inject audio into mic line and get output it tells you that your Balanced Modulator is working. In CW mode to produce output from the BM the Car Pot provides variable DC voltage to bias on the ring diodes. It is derives this bias voltage from regulated 9vdc from AVR board thru mode switch contacts.

The BM is on the IF board. Need to measure at Conn IF-5 at the CV terminal. Should see variable 0 to 9vdc at CV as you adjust the Car Pot thru its range.

Then measure at TP-2 and should see approx 0.0 to 0.70vdc as you adjust the Car Pot.

Thanks for the comments.

1) I have 60 ma of current when I flip Send switch in CW, USB, and LSB modes. I don't have a microphone as I only operated CW back when I was on the air. I have a 1KHz tone generator and connected it to the microphone input. When I do this and increase MIC control in both USB and LSB I am able to drive plate current to the same 160 ma (on 20 meters) that I get in the FSK mode. So it appears CW is the only mode that isn't functioning.

2) I tuned the rig to the max power out (IP 160 ma) into the dummy load in the FSK position. I then switch to CW mode but the IP stays at 60 ma. This is with the CAR control at max (10 mark). Bias voltage drops from -100 to -63 volts when I flip Send switch in CW mode.

3) In the FSK mode I get almost FSD with CAR control at max on 20 meters in the ALC position. I am only 2 tick marks away from FSD. On 80, 40, and 160 I am able to get FSD at lower levels of the CAR control. However, when I turn SG back on and tune, the plate dip is in the wrong position for 40 and 160. For both of those bands max dip is at the very low end of 3.5 dial marking. On 20, 15, and 10 the dip is in the correct position. On 10 I am only able to get 80 ma of plate current at min dip with CAR at max. This does indicate the 12BY7 is bad. I think I have a spare one somewhere around here - just have to look. When I switch to USB or LSB I am able to get the same levels of ALC deflection as FSK when I inject the 1 KHz. However, in CW mode I do not get any ALC meter deflection.

4) I will perform this step once the rig is working.

5) I am using the dummy load because I have a 40 meter dipole 8 feet off the ground (HOA) as my only antenna and not sure of the impedance it reflects. I have a Heath HM-15 SWR bridge but it doesn't have a watts reading. I just received an order from Mouser yesterday with the parts to build the dummy load that is on the K4EAA website. I am including the power measurement components so I will be able to know what my power out is. Once I am back on the air I will obtain an inline watt meter.

6) I haven't been on the air in 17 years and am wanting to get back on since I will be retiring in Jan and moving to somewhere that doesn't have a HOA. I have a HW-100 and a FT-101E that have sat in the garage for the last 17 years. I built the HW-100 back in 1968 and last used it in 1986. The FT-101 was working and I was using it on a daily basis when I went QRT at the end 1996. I bought this TS-820 10 years ago but have never used it. It has sat in the closet in my office since I bought it. I figured I would try to get it working first as it hasn't been exposed to extreme temperatures. I would be scared to power the other two up without replacing all the power supply caps first. My garage never drops below 100 four months out of the year.

1. In LSB/USB should be 60ma resting plate current when you flip to send or key the mic. No indication on RF meter position until you modulate the rig (speak in mic). Can you see and adjust the resting plate current in SSB mode?

2. In Tune/CW will be plate current when you have RF drive (Car Pot advanced) only if you have RF drive as indicated by peaking the ALC indication with the Drive control.

Are you certain that Aux and TR relays are keying when you flip to send or key the mic? Sounds like they are based on seeing tube voltage dropping. Bias voltage at Finals control grid better not be dropping only 10%. It should change from approx -100vdc cutoff bias to approx -55vdc operating bias. If not then plate current and no RF output.

3. You can try a new 12BY7A as easy to do, but your rig has the diagnostic meter you need. Turn off SG switch and place rig in CW mode and peak the ALC indication by advancing the Car pot. Should be able to get full scale meter deflection (FSD) and hold there a few

seconds on each band without the ALC indication falling off. Should get FSD with Car Pot advanced no more than approx 1000 to 1100. Rest between each band test as Driver tube is running class A (full plate current).

4 If RF detector is pegging at 70ma plate current then turn down the sensitivity pot. You always have to adjust the sensitivity pot. Set it for approx 2/3 deflection at 100 watts out. Would have been handy if KW would have put the pot on the front panel. They provided this meter position as it is better to load a Class AB1 linear amp by tuning for max rf output without exceeding plate dissipation than using the old dip and load method. They also provided it as external wattmeters were not common and they wanted the radio to be instrumented to be stand alone.

5. I would not use a 50 watt dummy load. If you must then have to realize all dummy loads have a duty cycle. Can use it but have to limit key down time.

6. When you get a couple of bucks ahead suggest you get an external wattmeter. Makes a good Loading aid and a good diagnostic tool. Drake W4, Heath HM-102, any of the MFJs are good and give you a SWR bridge and Wattmeter in one piece of test gear. Having actual output wattage tells you a lot more than looking at relative RF output power by measuring rf voltage at SO-239 or measuring the temperature of your dummy load.

I have a Kenwood TS-820S. Receive is working fine. Strange transmit problem.

When the Mode switch is the Tune, CW, USB, or LSB postion and I operate the Send switch I get no plate current and no output. When the switch is in the FSK position, I get almost normal plate current and can tune the rig to about 3/4 full power out. I can only get the load and plate controls to 160 ma into my dummy load with carrier control at max. Maybe a bad 12BY7 preventing full power out.

The other strange thing is when the meter switch is in the RF position, I can only increase the carrier control to about 70 ma plate current before the meter pegs when in FSK mode.

My 50 watt dummy load doesn't have a power indicator but I know the transmitter is putting out decent power in FSK mode as the resistors in the dummy load are getting warm.

Voltages (SG, Plate, Bias) are all normal. They drop about 10% when switching from receive to transmit mode. This drop happens in all postions of the mode switch, not just the FSK mode.

This makes no sense as in most cases the Tune and CW contacts of S6 are tied together. And S6-2 ties Tune, CW, and FSK together. Has anyone seen this issue before or give me an idea where to look for the problem?

Ray

I forgot to mention where I am going with this (if not obvious) is a bad/dirty Mode switch contact or a broken wire at the mode switch in CW mode. The fact that you have output in FSK tells me that you do have approx 0.0 to 0.60vdc at TP-2 which then means the path from CV to the BM is good.

If you have no DMM, VOM, or VTVM the mode switch in a TS820 is an open deck type and pretty accessible with bottom cover off so you should be able to apply some deoxit and canned air to clean the contacts.

OK well that would have been a quick fix and not first time so had to ask.

What test gear do you have and what is your comfort level to take measurements inside the rig?

When you inject audio into mic line and get output it tells you that your Balanced Modulator is working. In CW mode to produce output from the BM the Car Pot provides variable DC voltage to bias on the ring diodes. It is derives this bias voltage from regulated 9vdc from AVR board thru mode switch contacts.

The BM is on the IF board. Need to measure at Conn IF-5 at the CV terminal. Should see variable 0 to 9vdc at CV as you adjust the Car Pot thru its range.

Then measure at TP-2 and should see approx 0.0 to 0.70vdc as you adjust the Car Pot.

Ray:

Do you have a key in the key jack? If so remove it or key the key with Car Pot advanced. Cant load rig in CW mode if you have a key in key jack and it isnt closed. Brings back memories of the J-38 slider bar.

We can talk about plate dip not occurring at right place when we get CW working.

Chris:

Havent see any responses? Apologize in advance to all for length of this.

I previously responded regards my experience with installing 1N5711/1N6263 diodes in TS-830 Product Detectors and how I matched them. I related that I did not perform any before and after testing and could only relate subjective results based on my ear. I noticed no striking difference. I think we also talked about external DSP audio filters and DSP speakers.

I am not sure why others are not responding regards their experience with replacing germanium ring diodes with hot carrier diodes in whatever KW hybrid model they operate. I suspect you would be interested in hearing results anecdotal or otherwise. This was a hot topic on this and most of the other major ham radio forums not too long ago and I am quite sure others did this mod on their Hybrids. I know they did on their Heathkit transceivers as well.

Come on fellows speak up here and help out this member!

Another contributor to your high noise floor may be harmonic content of the LO getting past the CRC Low Pass Filter at the output of the Product Detector. If this constant “hiss” is covering up S2 signals then clearly a problem. It would be interesting to measure the MDS and the AGC threshold, but suspect you don’t have the test gear to do that..

I am not sure how familiar you are with ring diode product detectors or the audio Low Pass Filter that follows them, so this may be old news for you but may help another. The LO that feeds the Product Detector is pretty high level. Approx 1.0 rms rf volts or +13dBm. You want this high injection level to ensure that the LO is switching the ring diodes and not the IF so that IMD will be lower. Since the LO level determines the diode current (typically less than 10ma) then having ring diodes with closely matched junction capacitance and forward voltage is important for optimum performance.

I am no hot carrier diode expert but I believe that they should be speced for what they refer to as Barrier Height or Drive Level. Will see it listed on data sheets commonly as Low, Medium, and High. I am guessing that a Medium drive level diode is what you would need for a +13dBm LO?

You could try suspending a monolithic quad package above the board, but I don’t think there would be much advantage? For a first attempt it would simply be easier to hand select individual Schottky diodes and see what noise reduction your ear detects. You also might want to measure LO signal level. Just don’t want it so low that the IF signal is switching the diodes.

Diode selection is not the only thing that contributes to the noise floor. The C-R-C Low Pass Filter at output of the detector is a critical component as well. Take a look at your schematic and your X-ray views of the Gen Board. The board may show a 1K resistor and

.001uf output cap. If these values are installed then the LPF would have a corner frequency of approx 159khz which would not work. The filter should be designed to have a corner frequency of no more than approx 3khz. I know this from limited testing. If you have a good audio sine wave generator with constant output and a AC millivolt meter you can inject approx 15 mv at the junction of D5/D6 and measure the filter output voltage at DET terminal and slowly sweep up in frequency from approx 2khz and log the frequency at 1dB, 2dB, and 3 dB to see where the corner is at. Here are my tests results on two TS-520 rigs and one TS-520S:
-1dB = 2300 hz
-2dB = 2650 hz
-3dB = 3075 hz (0.707 x input voltage level)

Part of the problem with the high LO injection level can be harmonic content ending up mixing and being present at the output of the Product Detector. If LPF is not designed properly or the RC values have changed then possible to have 5khz, 10khz, 10khz content in the DET audio output. The LPF RC constants are selected to address this. So it is possible that your LPF components are wrong or may have drifted in value. This is not very likely, but possible. It would be good to measure the LPF response if you could. I don’t measure it as matter of routine when I align a hybrid unless some performance issue.

If you look at this audio LPF in the TS520, TS820, and TS830 you will see different values for the capacitors and resistors. KW does not use a high Q inductor for the series R element. I think it would be better, but chokes cost more than resistors. KW messed with the LPF CRC values and the AGC RC time constant component values over time in the hybrids. Even made changes from the 1 million series TS-830 to the 4 million series. Not sure they ever got either where they really wanted.

TS-520 R = 6.8k and C = .047uf
TS-820 R = 4.7k and C = .022uf
TS-530 R = 6.8k and C = .033uf
TS-830 R = 2.7k and C = .022uf

So you can see KW has been messing with Product Detector LPF CRC values since day one.

If you are good with Op amps perhaps could experiment with something like a Sallen Active LPF in lieu of the CRC filter?

Not much practical help for you in this response. Just wanted to make sure you know that noise floor can be affected by the ring diodes, the LO injection level, the IF chain, and the performance of the audio Low Pass Filter at the Product Detector output.

I think if you cannot get any help from the TS520 owners who have the CW filter installed and/or have installed the 1N5711 diodes you could do this:

1. Inspect your LPF and make sure the CRC values are not as shown on the Xray view.
2. Measure LO injection level at the Gen Board. It should be close to 1.0 rms rf volts. Could experiment with the level.
3. Measure response of your Low Pass Filter if possible.
4. Try installing individual Schottky 1N5711 or similar diodes that you can match forward voltage as close as you can.
5. Try suspending a monolithic quad package in lieu of individual diodes.(a Mod)
6. Try different values for LPF CRC (use poly or mylar for the output cap)
7. Try suspending an active LPF in lieu of the CRC filter. (a Mod)

8. Try an outboard DSP audio filter. Might find a good used Idiom Press SCAF-1. Might ask on the forum if anyone is using DSP filters or DSP speakers with their TS-520 rigs.

Ok, I am back with this "problem". I will first admit that my reference radio is the top of the line flagship ICOM IC-761. This thing has a REALLY quiet and sensitive receiver. I LOVE my TS-520. I think it is a better radio for SSB. It is just wonderful to listen to, and I get complements about the transmit audio that I never get with the 761. It is a great armchair radio. However, this weekend I was chasing DX on the high bands, and this white noise problem was annoying enough to have me switch back to my 761 for the DX. I sent an email to a local ham friend to see if he has the CW filter installed so that I can listen to his receiver and compare it to another 520s. The white noise is still there even if I switch to FIX or a non existent EXT. VFO. This noise makes up about 50% of the noise floor on a very quiet band (like 10m when the band is barely open). However, again -- it is generated after the signal passes through the Narrow CW crystal lattice filter, but before the audio stage. It is reduced by decreasing the RF gain, but it is MUCH wider than the skirt of the filter. I am wondering if putting Schottky diodes in the balanced detector circuit might improve things -- or not.

Thoughts, opinions, flames? I might be just expecting too much from this old gal, but hopefully I can listen to someone else's radio before resigning myself to that.

Regards,
Chris Maness

45386. Kenwood Net Update (October 20, 2013)

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-20 19:03:02 UTC
From: Mark Gilger
Topic: 45386 Message: 45386

The Saturday net we had 20 check-in with
excellent band conditions. Jimmy, was supposed to
run the net, but had difficulties with his radio,
so I ran it with my TS-940S. W4OP checked in
running his TS-900. There are not a lot of those
radios around any more, so it□s good to hear one
check in every once in a while.

```
5 running TS-520(x)
3 running TS-530(x)
2 running TS-820(x)
3 running TS-830S
1 running TS-900

I was running my TS-940s.
```

The Sunday□s 20 meter net had 12 stations
checking in under good band conditions. Out of those, there was:

```
4 running TS-520(x)
1 running TS-530(x)
0 running TS-820(x)
1 running TS-830S

I was running my TS-820s.
```

We have been having several people checking in
regularly with their TS-430, TS-440, and
TS-940□s, which of course is not a hybrid,
although over 30+ years old. Everyone is welcome
as long as they have an interest in the older equipment.

```
If anyone would be interested in filling in as a
net control station, please send me an email.
Currently it's just myself, WB2KNR and WB0SGA. I
would like to get several more. If we do, we can
alternate so everyone might be on a 3-4 week
rotation. It's a lot of fun and a good way to
make sure you station is optimized.

For anyone that has not heard, we have a new web
site that WB4HFN is hosting. He currently has a
very nice site for Drake, Collins and Heathkit
and now Kenwood Hybrids. Good quality manuals
plus sale flyers and brochures will be found
here, along with user supplied information for all Hybrids.
```

His URL is:
<http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm>http://www.wb4hfn.com/KENWOOD/KenwoodHomePage.htm

To date, we have had the following check-in:

Nov. 2011 ☐ Oct. 2012 Saturday total 754
check-ins, Sunday total 563 check-ins

November 2012, Saturday☐s, net total = 47, Sundays total = 20
December 2012, Saturday☐s, net total = 74, Sunday☐s total = 70
January 2013, Saturday☐s, net total = 93, Sunday☐s total = 87
February 2013, Saturday☐s net total = 103, Sundays total = 87
March 2013, Saturday☐s, net total = 112, Sunday☐s total =39
April 2013, Saturday☐s net total = 52, Sunday☐s total = 29
May 2013, Saturday☐s net total = 45, Sunday☐s total = 50
June 2013, Saturday☐s net total = 30, Sunday☐s total = 27
July 2013, Saturday☐s net total = 63, Sunday☐s total = 41
August 2013, Saturday☐s net total = 82, Sunday☐s total = 50
September 2013, Saturday☐s net total = 66, Sunday☐s total = 54
October 2013, Saturday☐s net total = 45, Sunday☐s total = 47 (Month to date)

Net Info:

On Conn IF-5 CV the voltage varies from .1 volts to 8.95 volts as I rotate the CAR control. On TP-2 the voltage varies from 16 mV to .443 volts as I rotate the CAR control. These voltages are the same with the Mode switch in either CW or FSK mode.

Also, on the FIX VOX board, FIX3-11 is shorted to ground when the key is not plugged in. If I plug the key in, FIX3-11 follows the key, open with key up, ground with key down. I cleaned the mode switch and visually checked it for broken wires.

I have a couple of multimeters, a 150 MHz analog scope, a 100 MHz digital scope, a W7ZOI power meter, and a KA7EXM power meter. I feel comportable taking measurements anywhere inside the rig, including the final cage.

I forgot to mention where I am going with this (if not obvious) is a bad/dirty Mode switch contact or a broken wire at the mode switch in CW mode. The fact that you have output in FSK tells me that you do have approx 0.0 to 0.60vdc at TP-2 which then means the path from CV to the BM is good.

If you have no DMM, VOM, or VTVM the mode switch in a TS820 is an open deck type and pretty accessible with bottom cover off so you should be able to apply some deoxit and canned air to clean the contacts.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK well that would have been a quick fix and not first time so had to ask.

What test gear do you have and what is your comfort level to take measurements inside the rig?

When you inject audio into mic line and get output it tells you that your Balanced Modulator is working. In CW mode to produce output from the BM the Car Pot provides variable DC voltage to bias on the ring diodes. It is derives this bias voltage from regulated 9vdc from AVR board thru mode switch contacts.

The BM is on the IF board. Need to measure at Conn IF-5 at the CV terminal. Should see variable 0 to 9vdc at CV as you adjust the Car Pot thru its range.

Then measure at TP-2 and should see approx 0.0 to 0.70vdc as you adjust the Car Pot.

Ray:

Do you have a key in the key jack? If so remove it or key the key with Car Pot advanced. Cant load rig in CW mode if you have a key in key jack and it isnt closed. Brings back memories of the J-38 slider bar.

We can talk about plate dip not occurring at right place when we get CW working.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

Thanks for the comments.

1) I have 60 ma of current when I flip Send switch in CW, USB, and LSB modes. I don't have a microphone as I only operated CW back when I was on the air. I have a 1KHz tone generator and connected it to the microphone input. When I do this and increase MIC control in both USB and LSB I am able to drive plate current to the same 160 ma (on 20 meters) that I get in the FSK mode. So it appears CW is the only mode that isn't functioning.

2) I tuned the rig to the max power out (IP 160 ma) into the dummy load in the FSK position. I then switch to CW mode but the IP stays at 60 ma. This is with the CAR control at max (10 mark). Bias voltage drops from -100 to -63 volts when I flip Send switch in CW mode.

3) In the FSK mode I get almost FSD with CAR control at max on 20 meters in the ALC position. I am only 2 tick marks away from FSD. On 80, 40, and 160 I am able to get FSD at lower levels of the CAR control. However, when I turn SG back on and tune, the plate dip is in the wrong position for 40 and 160. For both of those bands max dip is at the very low end of 3.5 dial marking. On 20, 15, and 10 the dip is in the correct position. On 10 I am only able to get 80 ma of plate current at min dip with CAR at max. This does indicate the 12BY7 is bad. I think I have a spare one somewhere around here - just have to look. When I switch to USB or LSB I am able to get the same levels of ALC deflection as FSK when I inject the 1 KHz. However, in CW mode I do not get any ALC meter deflection.

4) I will perform this step once the rig is working.

5) I am using the dummy load because I have a 40 meter dipole 8 feet off the ground (HOA) as my only antenna and not sure of the impedance it reflects. I have a Heath HM-15 SWR bridge but it doesn't have a watts reading. I just received an order from Mouser yesterday with the parts to build the dummy load that is on the K4EAA website. I am including the power measurement components so I will be able to know what my power out is. Once I am back on the air I will obtain an inline watt meter.

6) I haven't been on the air in 17 years and am wanting to get back on since I will be retiring in Jan and moving to somewhere that doesn't have a HOA. I have a HW-100 and a

FT-101E that have sat in the garage for the last 17 years. I built the HW-100 back in 1968 and last used it in 1986. The FT-101 was working and I was using it on a daily basis when I went QRT at the end 1996. I bought this TS-820 10 years ago but have never used it. It has sat in the closet in my office since I bought it. I figured I would try to get it working first as it hasn't been exposed to extreme temperatures. I would be scared to power the other two up without replacing all the power supply caps first. My garage never drops below 100 four months out of the year.

Ray
AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

1. In LSB/USB should be 60ma resting plate current when you flip to send or key the mic. No indication on RF meter position until you modulate the rig (speak in mic). Can you see and adjust the resting plate current in SSB mode?

2. In Tune/CW will be plate current when you have RF drive (Car Pot advanced) only if you have RF drive as indicated by peaking the ALC indication with the Drive control.

Are you certain that Aux and TR relays are keying when you flip to send or key the mic? Sounds like they are based on seeing tube voltage dropping. Bias voltage at Finals control grid better not be dropping only 10%. It should change from approx -100vdc cutoff bias to approx -55vdc operating bias. If not then plate current and no RF output.

3. You can try a new 12BY7A as easy to do, but your rig has the diagnostic meter you need. Turn off SG switch and place rig in CW mode and peak the ALC indication by advancing the Car pot. Should be able to get full scale meter deflection (FSD) and hold there a few seconds on each band without the ALC indication falling off. Should get FSD with Car Pot advanced no more than approx 1000 to 1100. Rest between each band test as Driver tube is running class A (full plate current).

4 If RF detector is pegging at 70ma plate current then turn down the sensitivity pot. You always have to adjust the sensitivity pot. Set it for approx 2/3 deflection at 100 watts out. Would have been handy if KW would have put the pot on the front panel. They provided this meter position as it is better to load a Class AB1 linear amp by tuning for max rf output without exceeding plate dissipation than using the old dip and load method. They also provided it as external wattmeters were not common and they wanted the radio to be instrumented to be stand alone.

5. I would not use a 50 watt dummy load. If you must then have to realize all dummy loads have a duty cycle. Can use it but have to limit key down time.

6. When you get a couple of bucks ahead suggest you get an external wattmeter. Makes a good Loading aid and a good diagnostic tool. Drake W4, Heath HM-102, any of the MFJs are good and give you a SWR bridge and Wattmeter in one piece of test gear. Having actual output wattage tells you a lot more than looking at relative RF output power by measuring rf voltage at SO-239 or measuring the temperature of your dummy load.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

I have a Kenwood TS-820S. Receive is working fine. Strange transmit problem.

When the Mode switch is the Tune, CW, USB, or LSB postion and I operate the Send switch I get no plate current and no output. When the switch is in the FSK position, I get almost normal plate current and can tune the rig to about 3/4 full power out. I can only get the load and plate controls to 160 ma into my dummy load with carrier control at max. Maybe a bad 12BY7 preventing full power out.

The other strange thing is when the meter switch is in the RF position, I can only increase the carrier control to about 70 ma plate current before the meter pegs when in FSK mode.

My 50 watt dummy load doesn't have a power indicator but I know the transmitter is putting out decent power in FSK mode as the resistors in the dummy load are getting warm.

Voltages (SG, Plate, Bias) are all normal. They drop about 10% when switching from receive to transmit mode. This drop happens in all postions of the mode switch, not just the FSK mode.

This makes no sense as in most cases the Tune and CW contacts of S6 are tied together. And S6-2 ties Tune, CW, and FSK together. Has anyone seen this issue before or give me an idea where to look for the problem?

For some reason I cannot read your entire response? It appears you are reporting back that you have good bias voltage available at the BM from the Car Pot. In CW TX mode you need this bias voltage and you need the local oscillator (LO) or Carrier to produce an output. Which in this case it is 8.830.70mhz CA-2 produced on the CAR-2 Unit.

You are getting CA-2 Carrier in FSK mode so it tells me the Crystal and the soldering at its pins have to be good.

If you have a RF millivolt meter or O-scope you can measure the 8830.7 mhz Carrier at the IF board at TP-5.TP-5 is tucked back in the corner under the chassis side rail. With rig in CW mode flip to send and measure the level and the frequency at TP-5. It should be approx 300mv rms or approx 850mv P-P on a scope at 8830.70mhz.

I would measure the level first before you look at it with a Freq Counter as the counter may pull the level down. If you dont have a means to measure CA-2 Carrier level and frequency then at minimum measure CW terminal at CAR-2 Unit board to make sure you are getting CW TX bias voltage.

If you remove the 2 screws that secure the cover you will see a white 10 pin connector. The 3rd pin from the Crystal is the CW terminal. When you flip to send in CW mode should see approx 9.0vdc here. If you have 9vdc and still no output then suspect bad switching diode D1. D1 is close to the Crystal and you can measure the voltage at its anode and cathode. When you flip to send in CW mode should read approx 9vdc on the anode and approx 8.3vdc on the cathode. Note: The 9vdc will depend on where the AVR regulated 9vdc has been set too.

Let's try this again. For some reason yahoo has been mangling my posts. This has been a problem ever since they went to this new stupid format they are using.

Measuring at TP-2 the voltage varies from 16 mV to .443V when adjusting the CAR control in both FSK and CW mode. On Conn IF-5 at the CV terminal, the voltage varies from .12V to 8.95V in both FSK and CW mode when adjusting the CAR control.

Also, on the FIX VOX board FIX3-11 is grounded with no key plugged in. Plugging a key in, FIX3-11 follows the key (open key up, grounded key down).

I have cleaned the contacts on the Mode switch and checked for broken wires.

At TP-5 I measure 8.831434 MHz at .64V P-P (on scope) in all positions of the mode switch without the Send switch flipped. When I flip the Send switch the voltage drops to .48V P-P. The CAR control has no affect on the signal level with the Send switch in either position.

I measure 8.97V at the CW terminal on CAR-2 when I flip the Send switch. I measure 8.94V at the anode of D1 and 8.19V at the cathode when the Send switch is flipped.

I have a couple of multimeters, a 150 MHz analog scope, 100 MHz digital scope, W7ZOI power meter, and a KA7EXM power meter. I feel comfortable taking measurements anywhere inside the radio including the Final Cage.

For some reason I cannot read your entire response? It appears you are reporting back that you have good bias voltage available at the BM from the Car Pot. In CW TX mode you need this bias voltage and you need the local oscillator (LO) or Carrier to produce an output. Which in this case it is 8.830.70mhz CA-2 produced on the CAR-2 Unit.

You are getting CA-2 Carrier in FSK mode so it tells me the Crystal and the soldering at its pins have to be good.

If you have a RF millivolt meter or O-scope you can measure the 8830.7 mhz Carrier at the IF board at TP-5.TP-5 is tucked back in the corner under the chassis side rail. With rig in CW mode flip to send and measure the level and the frequency at TP-5. It should be approx 300mv rms or approx 850mv P-P on a scope at 8830.70mhz.

I would measure the level first before you look at it with a Freq Counter as the counter may pull the level down. If you dont have a means to measure CA-2 Carrier level and frequency then at minimum measure CW terminal at CAR-2 Unit board to make sure you are getting CW TX bias voltage.

If you remove the 2 screws that secure the cover you will see a white 10 pin connector. The 3rd pin from the Crystal is the CW terminal. When you flip to send in CW mode should see approx 9.0vdc here. If you have 9vdc and still no output then suspect bad switching diode

D1. D1 is close to the Crystal and you can measure the voltage at its anode and cathode. When you flip to send in CW mode should read approx 9vdc on the anode and approx 8.3vdc on the cathode. Note: The 9vdc will depend on where the AVR regulated 9vdc has been set too.

On Conn IF-5 CV the voltage varies from .1 volts to 8.95 volts as I rotate the CAR control. On TP-2 the voltage varies from 16 mV to .443 volts as I rotate the CAR control. These voltages are the same with the Mode switch in either CW or FSK mode.

Also, on the FIX VOX board, FIX3-11 is shorted to ground when the key is not plugged in. If I plug the key in, FIX3-11 follows the key, open with key up, ground with key down. I cleaned the mode switch and visually checked it for broken wires.

I have a couple of multimeters, a 150 MHz analog scope, a 100 MHz digital scope, a W7ZOI power meter, and a KA7EXM power meter. I feel comportable taking measurements anywhere inside the rig, including the final cage.

Ray

I forgot to mention where I am going with this (if not obvious) is a bad/dirty Mode switch contact or a broken wire at the mode switch in CW mode. The fact that you have output in FSK tells me that you do have approx 0.0 to 0.60vdc at TP-2 which then means the path from CV to the BM is good.

If you have no DMM, VOM, or VTVM the mode switch in a TS820 is an open deck type and pretty accessible with bottom cover off so you should be able to apply some deoxit and canned air to clean the contacts.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK well that would have been a quick fix and not first time so had to ask.

What test gear do you have and what is your comfort level to take measurements inside the rig?

When you inject audio into mic line and get output it tells you that your Balanced Modulator is working. In CW mode to produce output from the BM the Car Pot provides variable DC voltage to bias on the ring diodes. It is derives this bias voltage from regulated 9vdc from AVR board thru mode switch contacts.

The BM is on the IF board. Need to measure at Conn IF-5 at the CV terminal. Should see variable 0 to 9vdc at CV as you adjust the Car Pot thru its range.

Then measure at TP-2 and should see approx 0.0 to 0.70vdc as you adjust the Car Pot.

Terry,

No, I don't have a key in the key jack. However, I did plug one in and keyed it just to see if the N/C contact wasn't closing the circuit.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Do you have a key in the key jack? If so remove it or key the key with Car Pot advanced. Cant load rig in CW mode if you have a key in key jack and it isnt closed. Brings back memories of the J-38 slider bar.

We can talk about plate dip not occurring at right place when we get CW working.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

Thanks for the comments.

1) I have 60 ma of current when I flip Send switch in CW, USB, and LSB modes. I don't have a microphone as I only operated CW back when I was on the air. I have a 1KHz tone generator and connected it to the microphone input. When I do this and increase MIC control in both USB and LSB I am able to drive plate current to the same 160 ma (on 20 meters) that I get in the FSK mode. So it appears CW is the only mode that isn't functioning.

2) I tuned the rig to the max power out (IP 160 ma) into the dummy load in the FSK position. I then switch to CW mode but the IP stays at 60 ma. This is with the CAR control at max (10 mark). Bias voltage drops from -100 to -63 volts when I flip Send switch in CW mode.

3) In the FSK mode I get almost FSD with CAR control at max on 20 meters in the ALC position. I am only 2 tick marks away from FSD. On 80, 40, and 160 I am able to get FSD at lower levels of the CAR control. However, when I turn SG back on and tune, the plate dip is in the wrong position for 40 and 160. For both of those bands max dip is at the very low end of 3.5 dial marking. On 20, 15, and 10 the dip is in the correct position. On 10 I am only able to get 80 ma of plate current at min dip with CAR at max. This does indicate the 12BY7 is bad. I think I have a spare one somewhere around here - just have to look. When I switch to USB or LSB I am able to get the same levels of ALC deflection as FSK when I inject the 1 KHz. However, in CW mode I do not get any ALC meter deflection.

4) I will perform this step once the rig is working.

5) I am using the dummy load because I have a 40 meter dipole 8 feet off the ground (HOA) as my only antenna and not sure of the impedance it reflects. I have a Heath HM-15 SWR bridge but it doesn't have a watts reading. I just received an order from Mouser yesterday with the parts to build the dummy load that is on the K4EAA website. I am including the power measurement components so I will be able to know what my power out is. Once I am back on the air I will obtain an inline watt meter.

6) I haven't been on the air in 17 years and am wanting to get back on since I will be retiring in Jan and moving to somewhere that doesn't have a HOA. I have a HW-100 and a FT-101E that have sat in the garage for the last 17 years. I built the HW-100 back in 1968 and last used it in 1986. The FT-101 was working and I was using it on a daily basis when I went QRT at the end 1996. I bought this TS-820 10 years ago but have never used it. It has sat in the closet in my office since I bought it. I figured I would try to get it working first as it hasn't been exposed to extreme temperatures. I would be scared to power the other two up without replacing all the power supply caps first. My garage never drops below 100 four months out of the year.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

1. In LSB/USB should be 60ma resting plate current when you flip to send or key the mic. No indication on RF meter position until you modulate the rig (speak in mic). Can you see and adjust the resting plate current in SSB mode?

2. In Tune/CW will be plate current when you have RF drive (Car Pot advanced) only if you have RF drive as indicated by peaking the ALC indication with the Drive control.

Are you certain that Aux and TR relays are keying when you flip to send or key the mic? Sounds like they are based on seeing tube voltage dropping. Bias voltage at Finals control grid better not be dropping only 10%. It should change from approx -100vdc cutoff bias to approx -55vdc operating bias. If not then plate current and no RF output.

3. You can try a new 12BY7A as easy to do, but your rig has the diagnostic meter you need. Turn off SG switch and place rig in CW mode and peak the ALC indication by advancing the Car pot. Should be able to get full scale meter deflection (FSD) and hold there a few seconds on each band without the ALC indication falling off. Should get FSD with Car Pot advanced no more than approx 1000 to 1100. Rest between each band test as Driver tube is running class A (full plate current).

4 If RF detector is pegging at 70ma plate current then turn down the sensitivity pot. You always have to adjust the sensitivity pot. Set it for approx 2/3 deflection at 100 watts out. Would have been handy if KW would have put the pot on the front panel. They provided this meter position as it is better to load a Class AB1 linear amp by tuning for max rf output without exceeding plate dissipation than using the old dip and load method. They also provided it as external wattmeters were not common and they wanted the radio to be instrumented to be stand alone.

5. I would not use a 50 watt dummy load. If you must then have to realize all dummy loads have a duty cycle. Can use it but have to limit key down time.

6. When you get a couple of bucks ahead suggest you get an external wattmeter. Makes a good Loading aid and a good diagnostic tool. Drake W4, Heath HM-102, any of the MFJs are good and give you a SWR bridge and Wattmeter in one piece of test gear. Having actual output wattage tells you a lot more than looking at relative RF output power by measuring rf voltage at SO-239 or measuring the temperature of your dummy load.

I have a Kenwood TS-820S. Receive is working fine. Strange transmit problem.

When the Mode switch is the Tune, CW, USB, or LSB postion and I operate the Send switch I get no plate current and no output. When the switch is in the FSK position, I get almost normal plate current and can tune the rig to about 3/4 full power out. I can only get the load and plate controls to 160 ma into my dummy load with carrier control at max. Maybe a bad 12BY7 preventing full power out.

The other strange thing is when the meter switch is in the RF position, I can only increase the carrier control to about 70 ma plate current before the meter pegs when in FSK mode.

My 50 watt dummy load doesn't have a power indicator but I know the transmitter is putting out decent power in FSK mode as the resistors in the dummy load are getting warm.

Voltages (SG, Plate, Bias) are all normal. They drop about 10% when switching from receive to transmit mode. This drop happens in all postions of the mode switch, not just the FSK mode.

This makes no sense as in most cases the Tune and CW contacts of S6 are tied together. And S6-2 ties Tune, CW, and FSK together. Has anyone seen this issue before or give me an idea where to look for the problem?

Ray,
AB7HE

45390. RE: Re: Re: [TS-520_820_530_830] RE: Is a lot of White Noise normal with the CW RX Filter installed?

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-21 07:13:37 UTC
From: Chris Maness
Topic: 44803 Message: 45390

I will have to put this on my winter project list. The white noise is not so bad it drowns S2 signals, just makes it a strain to listen to the faint ones on low noise floor bands like 15 and 10m when the band is barely open. There is no S meter deflection. In my opinion there is a lot of white noise when a dummy load is connected. More than there should be on such an otherwise wonderful radio. I have been working on my DXCC, so my go for blood radio is in the shack now. It is a IC-761. The noise floor on that radio is phenomenal. It is nearly the same receiver as the 751A. However it is no where near as fun to use as my 520s. The Kenwood has better SSB audio on transmit and receive. Heck I even get many complements on the 120s with both the MC-30s and the MC-50. They say it is broadcast quality. Kenwood had the SSB sound quality nailed. The 520s really shines in armchair QSOs. Just wonderful.

Thanks,
Chris KQ6UP

Yes this new format gives me problems as well.

1. You are getting proper dc bias voltage to the BM. You need to confirm you are getting the Carrier Osc signal.

2. You cannot measure any Carrier freq or level at TP-5 in RX for any position of the mode switch. You may read some leakage signals in RX mode but meaningless. The BM is only used for TX and not RX. Only time you can measure any meaningful Carrier Osc frequency or level at TP-5 is in TX with the mode switch in CW or FSK. Carrier in RX mode is applied to another Mixer called the Product Detector and it arrives at IF board on IF-4 C1A terminal. You have separate Carrier Oscillators for RX and TX.

Also, the Car Level Pot has nothing to do with the Carrier Osc levels produced on the CAR Assembly Unit. The Car level pot unbalances the balanced modulator and determines the carrier output level from the BM.

You really need to measure CA-2 produced on the CAR-2 board. If you do not have 300mv of 8830.7mhz at TP-5 in CW mode when you flip to Send then you have to work your way back from TP-5 to CAR-2 board. CA2 can be checked on the 7th terminal up on the white terminal block on the CAR-2 board. On the IF board it comes in on Conn IF-5 pin 13.

At this point you have not confirmed that you have CAR-2 Q1 Oscillator running and available.

3. The DC voltages that you measured at D1 prove that you are getting the turn on voltages for Buffer amp Q2 so if Q1 is oscillating should get CW TX Carrier at CJ-3 and on to the IF board if all connectors are good.

You may have to adjust the frequency and output level but can talk about that later.

Suggest you buy a Freq Counter. Can measure Freq roughly with O-scope. Some measure and display Freq (may or may not do so accurately) and some require using F=1/T and not accurate enough for adjusting the Oscillators in the KW hybrids.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Let's try this again. For some reason yahoo has been mangling my posts. This has been a problem ever since they went to this new stupid format they are using.

Measuring at TP-2 the voltage varies from 16 mV to .443V when adjusting the CAR control in both FSK and CW mode. On Conn IF-5 at the CV terminal, the voltage varies from .12V to 8.95V in both FSK and CW mode when adjusting the CAR control.

Also, on the FIX VOX board FIX3-11 is grounded with no key plugged in. Plugging a key in, FIX3-11 follows the key (open key up, grounded key down).

I have cleaned the contacts on the Mode switch and checked for broken wires.

At TP-5 I measure 8.831434 MHz at .64V P-P (on scope) in all positions of the mode switch without the Send switch flipped. When I flip the Send switch the voltage drops to .48V P-P. The CAR control has no affect on the signal level with the Send switch in either position.

I measure 8.97V at the CW terminal on CAR-2 when I flip the Send switch. I measure 8.94V at the anode of D1 and 8.19V at the cathode when the Send switch is flipped.

I have a couple of multimeters, a 150 MHz analog scope, 100 MHz digital scope, W7ZOI power meter, and a KA7EXM power meter. I feel comfortable taking measurements anywhere inside the radio including the Final Cage.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

For some reason I cannot read your entire response? It appears you are reporting back that you have good bias voltage available at the BM from the Car Pot. In CW TX mode you need this bias voltage and you need the local oscillator (LO) or Carrier to produce an output. Which in this case it is 8.830.70mhz CA-2 produced on the CAR-2 Unit.

You are getting CA-2 Carrier in FSK mode so it tells me the Crystal and the soldering at its pins have to be good.

If you have a RF millivolt meter or O-scope you can measure the 8830.7 mhz Carrier at the IF board at TP-5.TP-5 is tucked back in the corner under the chassis side rail. With rig in CW mode flip to send and measure the level and the frequency at TP-5. It should be approx 300mv rms or approx 850mv P-P on a scope at 8830.70mhz.

I would measure the level first before you look at it with a Freq Counter as the counter may pull the level down. If you dont have a means to measure CA-2 Carrier level and frequency then at minimum measure CW terminal at CAR-2 Unit board to make sure you are getting CW TX bias voltage.

If you remove the 2 screws that secure the cover you will see a white 10 pin connector. The 3rd pin from the Crystal is the CW terminal. When you flip to send in CW mode should see approx 9.0vdc here. If you have 9vdc and still no output then suspect bad switching diode D1. D1 is close to the Crystal and you can measure the voltage at its anode and cathode. When you flip to send in CW mode should read approx 9vdc on the anode and approx 8.3vdc on the cathode. Note: The 9vdc will depend on where the AVR regulated 9vdc has been set too.

I forgot to mention where I am going with this (if not obvious) is a bad/dirty Mode switch contact or a broken wire at the mode switch in CW mode. The fact that you have output in FSK tells me that you do have approx 0.0 to 0.60vdc at TP-2 which then means the path from CV to the BM is good.

If you have no DMM, VOM, or VTVM the mode switch in a TS820 is an open deck type and pretty accessible with bottom cover off so you should be able to apply some deoxit and canned air to clean the contacts.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK well that would have been a quick fix and not first time so had to ask.

What test gear do you have and what is your comfort level to take measurements inside the rig?

When you inject audio into mic line and get output it tells you that your Balanced Modulator is working. In CW mode to produce output from the BM the Car Pot provides variable DC voltage to bias on the ring diodes. It is derives this bias voltage from regulated 9vdc from AVR board thru mode switch contacts.

The BM is on the IF board. Need to measure at Conn IF-5 at the CV terminal. Should see variable 0 to 9vdc at CV as you adjust the Car Pot thru its range.

Then measure at TP-2 and should see approx 0.0 to 0.70vdc as you adjust the Car Pot.

We can talk about plate dip not occurring at right place when we get CW working.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

Thanks for the comments.

1) I have 60 ma of current when I flip Send switch in CW, USB, and LSB modes. I don't have a microphone as I only operated CW back when I was on the air. I have a 1KHz tone generator and connected it to the microphone input. When I do this and increase MIC control in both USB and LSB I am able to drive plate current to the same 160 ma (on 20 meters) that I get in the FSK mode. So it appears CW is the only mode that isn't functioning.

2) I tuned the rig to the max power out (IP 160 ma) into the dummy load in the FSK position. I then switch to CW mode but the IP stays at 60 ma. This is with the CAR control at max (10 mark). Bias voltage drops from -100 to -63 volts when I flip Send switch in CW mode.

3) In the FSK mode I get almost FSD with CAR control at max on 20 meters in the ALC position. I am only 2 tick marks away from FSD. On 80, 40, and 160 I am able to get FSD at lower levels of the CAR control. However, when I turn SG back on and tune, the plate dip is in the wrong position for 40 and 160. For both of those bands max dip is at the very low end of 3.5 dial marking. On 20, 15, and 10 the dip is in the correct position. On 10 I am only able to get 80 ma of plate current at min dip with CAR at max. This does indicate the 12BY7 is bad. I think I have a spare one somewhere around here - just have to look. When I switch to USB or LSB I am able to get the same levels of ALC deflection as FSK when I inject the 1 KHz. However, in CW mode I do not get any ALC meter deflection.

4) I will perform this step once the rig is working.

5) I am using the dummy load because I have a 40 meter dipole 8 feet off the ground (HOA) as my only antenna and not sure of the impedance it reflects. I have a Heath HM-15 SWR bridge but it doesn't have a watts reading. I just received an order from Mouser yesterday with the parts to build the dummy load that is on the K4EAA website. I am including the power measurement components so I will be able to know what my power out is. Once I am back on the air I will obtain an inline watt meter.

6) I haven't been on the air in 17 years and am wanting to get back on since I will be retiring in Jan and moving to somewhere that doesn't have a HOA. I have a HW-100 and a FT-101E that have sat in the garage for the last 17 years. I built the HW-100 back in 1968 and last used it in 1986. The FT-101 was working and I was using it on a daily basis when I went QRT at the end 1996. I bought this TS-820 10 years ago but have never used it. It has sat in the closet in my office since I bought it. I figured I would try to get it working first as it hasn't been exposed to extreme temperatures. I would be scared to power the other two up without replacing all the power supply caps first. My garage never drops below 100 four months out of the year.

Ray
AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

1. In LSB/USB should be 60ma resting plate current when you flip to send or key the mic. No indication on RF meter position until you modulate the rig (speak in mic). Can you see and adjust the resting plate current in SSB mode?

2. In Tune/CW will be plate current when you have RF drive (Car Pot advanced) only if you have RF drive as indicated by peaking the ALC indication with the Drive control.

Are you certain that Aux and TR relays are keying when you flip to send or key the mic? Sounds like they are based on seeing tube voltage dropping. Bias voltage at Finals control grid better not be dropping only 10%. It should change from approx -100vdc cutoff bias to approx -55vdc operating bias. If not then plate current and no RF output.

3. You can try a new 12BY7A as easy to do, but your rig has the diagnostic meter you need. Turn off SG switch and place rig in CW mode and peak the ALC indication by advancing the Car pot. Should be able to get full scale meter deflection (FSD) and hold there a few seconds on each band without the ALC indication falling off. Should get FSD with Car Pot advanced no more than approx 1000 to 1100. Rest between each band test as Driver tube is running class A (full plate current).

4 If RF detector is pegging at 70ma plate current then turn down the sensitivity pot. You always have to adjust the sensitivity pot. Set it for approx 2/3 deflection at 100 watts out. Would have been handy if KW would have put the pot on the front panel. They provided this meter position as it is better to load a Class AB1 linear amp by tuning for max rf output without exceeding plate dissipation than using the old dip and load method. They also provided it as external wattmeters were not common and they wanted the radio to be instrumented to be stand alone.

5. I would not use a 50 watt dummy load. If you must then have to realize all dummy loads have a duty cycle. Can use it but have to limit key down time.

6. When you get a couple of bucks ahead suggest you get an external wattmeter. Makes a good Loading aid and a good diagnostic tool. Drake W4, Heath HM-102, any of the MFJs are good and give you a SWR bridge and Wattmeter in one piece of test gear. Having actual output wattage tells you a lot more than looking at relative RF output power by measuring rf voltage at SO-239 or measuring the temperature of your dummy load.

I have a Kenwood TS-820S. Receive is working fine. Strange transmit problem.

When the Mode switch is the Tune, CW, USB, or LSB postion and I operate the Send switch I get no plate current and no output. When the switch is in the FSK position, I get almost normal plate current and can tune the rig to about 3/4 full power out. I can only get the load and plate controls to 160 ma into my dummy load with carrier control at max. Maybe a bad 12BY7 preventing full power out.

The other strange thing is when the meter switch is in the RF position, I can only increase the carrier control to about 70 ma plate current before the meter pegs when in FSK mode.

My 50 watt dummy load doesn't have a power indicator but I know the transmitter is putting out decent power in FSK mode as the resistors in the dummy load are getting warm.

Voltages (SG, Plate, Bias) are all normal. They drop about 10% when switching from receive to transmit mode. This drop happens in all postions of the mode switch, not just the FSK mode.

This makes no sense as in most cases the Tune and CW contacts of S6 are tied together. And S6-2 ties Tune, CW, and FSK together. Has anyone seen this issue before or give me an idea where to look for the problem?

Ray,
AB7HE

I forgot to mention if you want to see with your test gear what a "normal" TX Carrier Osc signal looks like at TP-5 place mode switch to FSK and flip to send. If FSK is working in TX mode as you previously described you will have approx 850mv P-P at 8830.7 mhz at TP-5.

Terry

1. In LSB/USB should be 60ma resting plate current when you flip to send or key the mic. No indication on RF meter position until you modulate the rig (speak in mic). Can you see and adjust the resting plate current in SSB mode?

2. In Tune/CW will be plate current when you have RF drive (Car Pot advanced) only if you have RF drive as indicated by peaking the ALC indication with the Drive control.

Are you certain that Aux and TR relays are keying when you flip to send or key the mic? Sounds like they are based on seeing tube voltage dropping. Bias voltage at Finals control grid better not be dropping only 10%. It should change from approx -100vdc cutoff bias to approx -55vdc operating bias. If not then plate current and no RF output.

3. You can try a new 12BY7A as easy to do, but your rig has the diagnostic meter you need. Turn off SG switch and place rig in CW mode and peak the ALC indication by advancing the Car pot. Should be able to get full scale meter deflection (FSD) and hold there a few seconds on each band without the ALC indication falling off. Should get FSD with Car Pot advanced no more than approx 1000 to 1100. Rest between each band test as Driver tube is running class A (full plate current).

4 If RF detector is pegging at 70ma plate current then turn down the sensitivity pot. You always have to adjust the sensitivity pot. Set it for approx 2/3 deflection at 100 watts out. Would have been handy if KW would have put the pot on the front panel. They provided this meter position as it is better to load a Class AB1 linear amp by tuning for max rf output without exceeding plate dissipation than using the old dip and load method. They also provided it as external wattmeters were not common and they wanted the radio to be instrumented to be stand alone.

5. I would not use a 50 watt dummy load. If you must then have to realize all dummy loads have a duty cycle. Can use it but have to limit key down time.

6. When you get a couple of bucks ahead suggest you get an external wattmeter. Makes a good Loading aid and a good diagnostic tool. Drake W4, Heath HM-102, any of the MFJs are good and give you a SWR bridge and Wattmeter in one piece of test gear. Having actual output wattage tells you a lot more than looking at relative RF output power by measuring rf voltage at SO-239 or measuring the temperature of your dummy load.

I have a Kenwood TS-820S. Receive is working fine. Strange transmit problem.

When the Mode switch is the Tune, CW, USB, or LSB postion and I operate the Send switch I get no plate current and no output. When the switch is in the FSK position, I get almost normal plate current and can tune the rig to about 3/4 full power out. I can only get the load and plate controls to 160 ma into my dummy load with carrier control at max. Maybe a bad 12BY7 preventing full power out.

The other strange thing is when the meter switch is in the RF position, I can only increase the carrier control to about 70 ma plate current before the meter pegs when in FSK mode.

My 50 watt dummy load doesn't have a power indicator but I know the transmitter is putting out decent power in FSK mode as the resistors in the dummy load are getting warm.

Voltages (SG, Plate, Bias) are all normal. They drop about 10% when switching from receive to transmit mode. This drop happens in all postions of the mode switch, not just the FSK mode.

This makes no sense as in most cases the Tune and CW contacts of S6 are tied together. And S6-2 ties Tune, CW, and FSK together. Has anyone seen this issue before or give me an idea where to look for the problem?

Ray:

I mis-spoke in Item 2 when I said you cant measure carrier at TP-5 in Rx in any of the mode switch positions. There will be legitimate carrier but not of interest.

There will be Carrier at CA-2 and TP-5 in Rx in all positions of the mode switch that you should see, but it is meaningless for CW Tx operation. It was not correct for me to label it as "Leakage" signals.

It is there by design but not for Rx or Tx operation. CA-1 Carrier Osc signals are coupled to the CAR-2 board to amp Q3 and then on to TP-5 at IF board and then sampled and sent to the CCR lead to provide carrier oscillator signals for the Counter Mixer Board. So the carrier osc signals you were measuring at each position of the mode switch in Rx are there by design to feed the counter, but of no interest to us as not utilized for the BM and CW transmit.

So you will see approx 250mv rms at 8831.50 mhz in CW and LSB and 250mv at 8828.5mhz in LSB and FSK, but not used by the BM. BM is not used in Rx operation. So disregard these signal other than the low levels you measured cannot be correct if your counter is working properly. I suspect you are not using O-scope properly. Are you using a 10X probe?

What I meant to say is at CA-2 and TP-5 the only frequency and level we care about is in CW and FSK positions of the mode switch in Tx. CA-2 carrier oscillator should be approx 250mv rms @ 8830.70mhz when in CW and FSK mode when flipped to send. This is what you are trying to validate. Measure at TP-5 in FSK as you know it is working. So use it to get your O-scope set up correctly and you can see approx 850mv P-P at 8830.7mhz. Once you can read that on your O-scope now switch to CW mode and flip to send to measure carrier osc signal level at TP-5.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Yes this new format gives me problems as well.

1. You are getting proper dc bias voltage to the BM. You need to confirm you are getting the Carrier Osc signal.

2. You cannot measure any Carrier freq or level at TP-5 in RX for any position of the mode switch. You may read some leakage signals in RX mode but meaningless. The BM is only used for TX and not RX. Only time you can measure any meaningful Carrier Osc frequency or level at TP-5 is in TX with the mode switch in CW or FSK. Carrier in RX mode is applied to another Mixer called the Product Detector and it arrives at IF board on IF-4 C1A terminal. You have separate Carrier Oscillators for RX and TX.

Also, the Car Level Pot has nothing to do with the Carrier Osc levels produced on the CAR Assembly Unit. The Car level pot unbalances the balanced modulator and determines the carrier output level from the BM.

You really need to measure CA-2 produced on the CAR-2 board. If you do not have 300mv of 8830.7mhz at TP-5 in CW mode when you flip to Send then you have to work your way back from TP-5 to CAR-2 board. CA2 can be checked on the 7th terminal up on the white terminal block on the CAR-2 board. On the IF board it comes in on Conn IF-5 pin 13.

At this point you have not confirmed that you have CAR-2 Q1 Oscillator running and available.

3. The DC voltages that you measured at D1 prove that you are getting the turn on voltages for Buffer amp Q2 so if Q1 is oscillating should get CW TX Carrier at CJ-3 and on to the IF board if all connectors are good.

You may have to adjust the frequency and output level but can talk about that later.

Suggest you buy a Freq Counter. Can measure Freq roughly with O-scope. Some measure and display Freq (may or may not do so accurately) and some require using F=1/T and not accurate enough for adjusting the Oscillators in the KW hybrids.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Let's try this again. For some reason yahoo has been mangling my posts. This has been a problem ever since they went to this new stupid format they are using.

Measuring at TP-2 the voltage varies from 16 mV to .443V when adjusting the CAR control in both FSK and CW mode. On Conn IF-5 at the CV terminal, the voltage varies from .12V to 8.95V in both FSK and CW mode when adjusting the CAR control.

Also, on the FIX VOX board FIX3-11 is grounded with no key plugged in. Plugging a key in, FIX3-11 follows the key (open key up, grounded key down).

I have cleaned the contacts on the Mode switch and checked for broken wires.

At TP-5 I measure 8.831434 MHz at .64V P-P (on scope) in all positions of the mode switch without the Send switch flipped. When I flip the Send switch the voltage drops to .48V P-P. The CAR control has no affect on the signal level with the Send switch in either position.

I measure 8.97V at the CW terminal on CAR-2 when I flip the Send switch. I measure 8.94V at the anode of D1 and 8.19V at the cathode when the Send switch is flipped.

I have a couple of multimeters, a 150 MHz analog scope, 100 MHz digital scope, W7ZOI power meter, and a KA7EXM power meter. I feel comfortable taking measurements anywhere inside the radio including the Final Cage.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

For some reason I cannot read your entire response? It appears you are reporting back that you have good bias voltage available at the BM from the Car Pot. In CW TX mode you need this bias voltage and you need the local oscillator (LO) or Carrier to produce an output. Which in this case it is 8.830.70mhz CA-2 produced on the CAR-2 Unit.

You are getting CA-2 Carrier in FSK mode so it tells me the Crystal and the soldering at its pins have to be good.

If you have a RF millivolt meter or O-scope you can measure the 8830.7 mhz Carrier at the IF board at TP-5.TP-5 is tucked back in the corner under the chassis side rail. With rig in CW mode flip to send and measure the level and the frequency at TP-5. It should be approx 300mv rms or approx 850mv P-P on a scope at 8830.70mhz.

I would measure the level first before you look at it with a Freq Counter as the counter may pull the level down. If you dont have a means to measure CA-2 Carrier level and frequency then at minimum measure CW terminal at CAR-2 Unit board to make sure you are getting CW TX bias voltage.

If you remove the 2 screws that secure the cover you will see a white 10 pin connector. The 3rd pin from the Crystal is the CW terminal. When you flip to send in CW mode should see approx 9.0vdc here. If you have 9vdc and still no output then suspect bad switching diode D1. D1 is close to the Crystal and you can measure the voltage at its anode and cathode. When you flip to send in CW mode should read approx 9vdc on the anode and approx 8.3vdc on the cathode. Note: The 9vdc will depend on where the AVR regulated 9vdc has been set too.

Ray

I forgot to mention where I am going with this (if not obvious) is a bad/dirty Mode switch contact or a broken wire at the mode switch in CW mode. The fact that you have output in FSK tells me that you do have approx 0.0 to 0.60vdc at TP-2 which then means the path from CV to the BM is good.

If you have no DMM, VOM, or VTVM the mode switch in a TS820 is an open deck type and pretty accessible with bottom cover off so you should be able to apply some deoxit and canned air to clean the contacts.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK well that would have been a quick fix and not first time so had to ask.

What test gear do you have and what is your comfort level to take measurements inside the rig?

When you inject audio into mic line and get output it tells you that your Balanced Modulator is working. In CW mode to produce output from the BM the Car Pot provides variable DC voltage to bias on the ring diodes. It is derives this bias voltage from regulated 9vdc from AVR board thru mode switch contacts.

The BM is on the IF board. Need to measure at Conn IF-5 at the CV terminal. Should see variable 0 to 9vdc at CV as you adjust the Car Pot thru its range.

Then measure at TP-2 and should see approx 0.0 to 0.70vdc as you adjust the Car Pot.

Ray:

Do you have a key in the key jack? If so remove it or key the key with Car Pot advanced. Cant load rig in CW mode if you have a key in key jack and it isnt closed. Brings back memories of the J-38 slider bar.

We can talk about plate dip not occurring at right place when we get CW working.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

Thanks for the comments.

1) I have 60 ma of current when I flip Send switch in CW, USB, and LSB modes. I don't have a microphone as I only operated CW back when I was on the air. I have a 1KHz tone generator and connected it to the microphone input. When I do this and increase MIC control in both USB and LSB I am able to drive plate current to the same 160 ma (on 20 meters) that I get in the FSK mode. So it appears CW is the only mode that isn't functioning.

2) I tuned the rig to the max power out (IP 160 ma) into the dummy load in the FSK position. I then switch to CW mode but the IP stays at 60 ma. This is with the CAR control at max (10 mark). Bias voltage drops from -100 to -63 volts when I flip Send switch in CW mode.

3) In the FSK mode I get almost FSD with CAR control at max on 20 meters in the ALC position. I am only 2 tick marks away from FSD. On 80, 40, and 160 I am able to get FSD at lower levels of the CAR control. However, when I turn SG back on and tune, the plate dip is

in the wrong position for 40 and 160. For both of those bands max dip is at the very low end of 3.5 dial marking. On 20, 15, and 10 the dip is in the correct position. On 10 I am only able to get 80 ma of plate current at min dip with CAR at max. This does indicate the 12BY7 is bad. I think I have a spare one somewhere around here - just have to look. When I switch to USB or LSB I am able to get the same levels of ALC deflection as FSK when I inject the 1 KHz. However, in CW mode I do not get any ALC meter deflection.

4) I will perform this step once the rig is working.

5) I am using the dummy load because I have a 40 meter dipole 8 feet off the ground (HOA) as my only antenna and not sure of the impedance it reflects. I have a Heath HM-15 SWR bridge but it doesn't have a watts reading. I just received an order from Mouser yesterday with the parts to build the dummy load that is on the K4EAA website. I am including the power measurement components so I will be able to know what my power out is. Once I am back on the air I will obtain an inline watt meter.

6) I haven't been on the air in 17 years and am wanting to get back on since I will be retiring in Jan and moving to somewhere that doesn't have a HOA. I have a HW-100 and a FT-101E that have sat in the garage for the last 17 years. I built the HW-100 back in 1968 and last used it in 1986. The FT-101 was working and I was using it on a daily basis when I went QRT at the end 1996. I bought this TS-820 10 years ago but have never used it. It has sat in the closet in my office since I bought it. I figured I would try to get it working first as it hasn't been exposed to extreme temperatures. I would be scared to power the other two up without replacing all the power supply caps first. My garage never drops below 100 four months out of the year.

Topic: 45375 Message: 45394

This is what I am seeing:
TP-5 and CJ3-CA2 have the same levels in CW and FSK modes: 820mV P-P in RX mode. Flipping Send switch the level drops to 640mV P-P. I have a Tektronix 2445 Scope and have the probe in 10X to prevent loading the circuit.

Frequencies measured at CJ3-CA2:
RX mode FSK - 8.828414 - TX mode FSK 8.830620
RX mode LSB - 8.828414 - TX mode LSB 8.828579
RX mode USB - 8.831460 - TX mode USB 8.831625
RX mode CW - 8.831460 - TX mode CW 8.830777

Frequencies measured at TP-5:
RX mode FSK - 8.828410 - TX mode FSK 8.830616
RX mode LSB - 8.828410 - TX mode LSB 8.828575
RX mode USB - 8.831450 - TX mode USB 8.831622
RX mode CW - 8.831446 - TX mode CW 8.830773

I am using a Simpson 710 Frequency counter. Specs say 1 Meg input shunted by 30 pF. The slight differences in frequency readings between CJ3-CA2 and TP-5 is probably due to the cable capacitance of the cable between IF5-13 and CJ3-CA2.

I have been taking all of these measurements with the SG switch turned off and the heater switch turned off.

If you have a RF millivolt meter or O-scope you can measure the 8830.7 mhz Carrier at the IF board at TP-5.TP-5 is tucked back in the corner under the chassis side rail. With rig in CW mode flip to send and measure the level and the frequency at TP-5. It should be approx 300mv rms or approx 850mv P-P on a scope at 8830.70mhz.

I would measure the level first before you look at it with a Freq Counter as the counter may pull the level down. If you dont have a means to measure CA-2 Carrier level and frequency then at minimum measure CW terminal at CAR-2 Unit board to make sure you are getting CW TX bias voltage.

If you remove the 2 screws that secure the cover you will see a white 10 pin connector. The 3rd pin from the Crystal is the CW terminal. When you flip to send in CW mode should see approx 9.0vdc here. If you have 9vdc and still no output then suspect bad switching diode D1. D1 is close to the Crystal and you can measure the voltage at its anode and cathode. When you flip to send in CW mode should read approx 9vdc on the anode and approx 8.3vdc on the cathode. Note: The 9vdc will depend on where the AVR regulated 9vdc has been set too.

Terry,

Thanks for the comments.

1) I have 60 ma of current when I flip Send switch in CW, USB, and LSB modes. I don't have a microphone as I only operated CW back when I was on the air. I have a 1KHz tone generator and connected it to the microphone input. When I do this and increase MIC control in both USB and LSB I am able to drive plate current to the same 160 ma (on 20 meters) that I get in the FSK mode. So it appears CW is the only mode that isn't functioning.

2) I tuned the rig to the max power out (IP 160 ma) into the dummy load in the FSK position. I then switch to CW mode but the IP stays at 60 ma. This is with the CAR control at max (10 mark). Bias voltage drops from -100 to -63 volts when I flip Send switch in CW mode.

3) In the FSK mode I get almost FSD with CAR control at max on 20 meters in the ALC position. I am only 2 tick marks away from FSD. On 80, 40, and 160 I am able to get FSD at lower levels of the CAR control. However, when I turn SG back on and tune, the plate dip is in the wrong position for 40 and 160. For both of those bands max dip is at the very low end of 3.5 dial marking. On 20, 15, and 10 the dip is in the correct position. On 10 I am only able to get 80 ma of plate current at min dip with CAR at max. This does indicate the 12BY7 is bad. I think I have a spare one somewhere around here - just have to look. When I switch to USB or LSB I am able to get the same levels of ALC deflection as FSK when I inject the 1 KHz. However, in CW mode I do not get any ALC meter deflection.

4) I will perform this step once the rig is working.

5) I am using the dummy load because I have a 40 meter dipole 8 feet off the ground (HOA) as my only antenna and not sure of the impedance it reflects. I have a Heath HM-15 SWR bridge but it doesn't have a watts reading. I just received an order from Mouser yesterday with the parts to build the dummy load that is on the K4EAA website. I am including the power measurement components so I will be able to know what my power out is. Once I am back on the air I will obtain an inline watt meter.

6) I haven't been on the air in 17 years and am wanting to get back on since I will be retiring in Jan and moving to somewhere that doesn't have a HOA. I have a HW-100 and a FT-101E that have sat in the garage for the last 17 years. I built the HW-100 back in 1968 and last used it in 1986. The FT-101 was working and I was using it on a daily basis when I went QRT at the end 1996. I bought this TS-820 10 years ago but have never used it. It has sat in the closet in my office since I bought it. I figured I would try to get it working first as it hasn't been exposed to extreme temperatures. I would be scared to power the other two up without replacing all the power supply caps first. My garage never drops below 100 four months out of the year.

1. In LSB/USB should be 60ma resting plate current when you flip to send or key the mic. No indication on RF meter position until you modulate the rig (speak in mic). Can you see and adjust the resting plate current in SSB mode?

2. In Tune/CW will be plate current when you have RF drive (Car Pot advanced) only if you have RF drive as indicated by peaking the ALC indication with the Drive control.

Are you certain that Aux and TR relays are keying when you flip to send or key the mic? Sounds like they are based on seeing tube voltage dropping. Bias voltage at Finals control grid better not be dropping only 10%. It should change from approx -100vdc cutoff bias to approx -55vdc operating bias. If not then plate current and no RF output.

3. You can try a new 12BY7A as easy to do, but your rig has the diagnostic meter you need. Turn off SG switch and place rig in CW mode and peak the ALC indication by advancing the Car pot. Should be able to get full scale meter deflection (FSD) and hold there a few seconds on each band without the ALC indication falling off. Should get FSD with Car Pot advanced no more than approx 1000 to 1100. Rest between each band test as Driver tube is running class A (full plate current).

4 If RF detector is pegging at 70ma plate current then turn down the sensitivity pot. You always have to adjust the sensitivity pot. Set it for approx 2/3 deflection at 100 watts out. Would have been handy if KW would have put the pot on the front panel. They provided this meter position as it is better to load a Class AB1 linear amp by tuning for max rf output without exceeding plate dissipation than using the old dip and load method. They also provided it as external wattmeters were not common and they wanted the radio to be instrumented to be stand alone.

5. I would not use a 50 watt dummy load. If you must then have to realize all dummy loads have a duty cycle. Can use it but have to limit key down time.

6. When you get a couple of bucks ahead suggest you get an external wattmeter. Makes a good Loading aid and a good diagnostic tool. Drake W4, Heath HM-102, any of the MFJs are good and give you a SWR bridge and Wattmeter in one piece of test gear. Having actual output wattage tells you a lot more than looking at relative RF output power by measuring rf voltage at SO-239 or measuring the temperature of your dummy load.

I have a Kenwood TS-820S. Receive is working fine. Strange transmit problem.

When the Mode switch is the Tune, CW, USB, or LSB postion and I operate the Send switch I get no plate current and no output. When the switch is in the FSK position, I get almost normal plate current and can tune the rig to about 3/4 full power out. I can only get the load and plate controls to 160 ma into my dummy load with carrier control at max. Maybe a bad 12BY7 preventing full power out.

The other strange thing is when the meter switch is in the RF position, I can only increase the carrier control to about 70 ma plate current before the meter pegs when in FSK mode.

My 50 watt dummy load doesn't have a power indicator but I know the transmitter is putting out decent power in FSK mode as the resistors in the dummy load are getting warm.

Voltages (SG, Plate, Bias) are all normal. They drop about 10% when switching from receive to transmit mode. This drop happens in all postions of the mode switch, not just the FSK mode.

This makes no sense as in most cases the Tune and CW contacts of S6 are tied together. And S6-2 ties Tune, CW, and FSK together. Has anyone seen this issue before or give me an idea where to look for the problem?

Ray,
AB7HE

Ray:

Good job. Much better.

If I understand your chart you are telling me that you have approx 640mv P-P @ 8.83077 at TP-5 in CW mode with rig flipped to Send (heaters off and SG switch off). 900mv P-P is attainable by adjusting T1 on CAR-2 board, but can do later unless you want to peak it now. 640mv will work for testing.

If this is true then you have confirmed that you have the two things you need at the Balanced Mod to produce RF output from it in CW mode. 1. Offset bias voltage and 2. Proper Carrier freq and level.

From the BM output the CW signal is routed to the Crystal IF Filter and then to Q1 the Transmit IF Amp or TIF amp. TIF signal leaves the IF board and is routed to the RF board to the TX Mixer where it is mixed with VCO to produce the actual transmit rf drive signal. No TIF signal and there will be no RF drive and no RF output. Also no VCO or low VCO level and no rf drive. Lets validate that we have TIF signal in CW mode first.

Unfortunately KW didnt provide a nice test point at the output of the Balanced Mod to measure the DSBSC signal in SSB mode or the Carrier in CW mode. However, you can get on the Drain of Q10 with a hat pin or floral arrangement pin and mini-grabber test lead. If you locate the BM ring diodes D26-D29 and then output Xfmr T10 you will see Q10. It is a metal can dual gate mosfet. Looking down on the can the Drain is the upper right lead. You should read approx 800mv P-P here. This signal is routed to the Xtal filter thru switcing diodes.

Do you have the CW filter installed. It is rare but could have a bad filter. More common to have a bad switching diode.

After signal passes thru the Xtal filter it is applied to Gate 1 of TIF amp Q1. It is also a metal can dual gate mosfet and sits outside and almost between the two filters at the inboard end. Looking down on Q1 Gate 1 is at 1200. Should have approx 160mv P-P here. The Drain is at 0600 and should have approx 1000mv P-P. TIF output is on Conn IF-3 Pin 2 and should have approx 850mv P-P here. You can jump right to measuring TIF output if you want and if good then off to the RF board.

We know that you have TIF output in FSK mode as you reported good RF output in that mode. I dont kow if you keyed rig in FSK and noted the 170hz shift or not, but not important right now. Also, you should have noted that the RF output in FSK is lower as the 820 lowers the Finals Screen Grid voltage in FSK mode so the tubes plate dissipation is not exceeded in this high duty cycle mode.

That should be enough for now.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

This is what I am seeing:
TP-5 and CJ3-CA2 have the same levels in CW and FSK modes: 820mV P-P in RX mode. Flipping Send switch the level drops to 640mV P-P. I have a Tektronix 2445 Scope and have the probe in 10X to prevent loading the circuit.

Frequencies measured at CJ3-CA2:
RX mode FSK - 8.828414 - TX mode FSK 8.830620
RX mode LSB - 8.828414 - TX mode LSB 8.828579
RX mode USB - 8.831460 - TX mode USB 8.831625
RX mode CW - 8.831460 - TX mode CW 8.830777

Frequencies measured at TP-5:
RX mode FSK - 8.828410 - TX mode FSK 8.830616
RX mode LSB - 8.828410 - TX mode LSB 8.828575
RX mode USB - 8.831450 - TX mode USB 8.831622
RX mode CW - 8.831446 - TX mode CW 8.830773

I am using a Simpson 710 Frequency counter. Specs say 1 Meg input shunted by 30 pF. The slight differences in frequency readings between CJ3-CA2 and TP-5 is probably due to the cable capacitance of the cable between IF5-13 and CJ3-CA2.

I have been taking all of these measurements with the SG switch turned off and the heater switch turned off.

Ray:

I mis-spoke in Item 2 when I said you cant measure carrier at TP-5 in Rx in any of the mode switch positions. There will be legitimate carrier but not of interest.

There will be Carrier at CA-2 and TP-5 in Rx in all positions of the mode switch that you should see, but it is meaningless for CW Tx operation. It was not correct for me to label it as "Leakage" signals.

It is there by design but not for Rx or Tx operation. CA-1 Carrier Osc signals are coupled to the CAR-2 board to amp Q3 and then on to TP-5 at IF board and then sampled and sent to the CCR lead to provide carrier oscillator signals for the Counter Mixer Board. So the carrier osc signals you were measuring at each position of the mode switch in Rx are there by design to feed the counter, but of no interest to us as not utilized for the BM and CW transmit.

So you will see approx 250mv rms at 8831.50 mhz in CW and LSB and 250mv at 8828.5mhz in LSB and FSK, but not used by the BM. BM is not used in Rx operation. So disregard these signal other than the low levels you measured cannot be correct if your counter is working properly. I suspect you are not using O-scope properly. Are you using a 10X probe?

What I meant to say is at CA-2 and TP-5 the only frequency and level we care about is in CW and FSK positions of the mode switch in Tx. CA-2 carrier oscillator should be approx 250mv rms @ 8830.70mhz when in CW and FSK mode when flipped to send. This is what you are trying to validate. Measure at TP-5 in FSK as you know it is working. So use it to get your O-scope set up correctly and you can see approx 850mv P-P at 8830.7mhz. Once you can read

that on your O-scope now switch to CW mode and flip to send to measure carrier osc signal level at TP-5.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Yes this new format gives me problems as well.

1. You are getting proper dc bias voltage to the BM. You need to confirm you are getting the Carrier Osc signal.

2. You cannot measure any Carrier freq or level at TP-5 in RX for any position of the mode switch. You may read some leakage signals in RX mode but meaningless. The BM is only used for TX and not RX. Only time you can measure any meaningful Carrier Osc frequency or level at TP-5 is in TX with the mode switch in CW or FSK. Carrier in RX mode is applied to another Mixer called the Product Detector and it arrives at IF board on IF-4 C1A terminal. You have separate Carrier Oscillators for RX and TX.

Also, the Car Level Pot has nothing to do with the Carrier Osc levels produced on the CAR Assembly Unit. The Car level pot unbalances the balanced modulator and determines the carrier output level from the BM.

You really need to measure CA-2 produced on the CAR-2 board. If you do not have 300mv of 8830.7mhz at TP-5 in CW mode when you flip to Send then you have to work your way back from TP-5 to CAR-2 board. CA2 can be checked on the 7th terminal up on the white terminal block on the CAR-2 board. On the IF board it comes in on Conn IF-5 pin 13.

At this point you have not confirmed that you have CAR-2 Q1 Oscillator running and available.

3. The DC voltages that you measured at D1 prove that you are getting the turn on voltages for Buffer amp Q2 so if Q1 is oscillating should get CW TX Carrier at CJ-3 and on to the IF board if all connectors are good.

You may have to adjust the frequency and output level but can talk about that later.

Suggest you buy a Freq Counter. Can measure Freq roughly with O-scope. Some measure and display Freq (may or may not do so accurately) and some require using F=1/T and not accurate enough for adjusting the Oscillators in the KW hybrids.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Let's try this again. For some reason yahoo has been mangling my posts. This has been a problem ever since they went to this new stupid format they are using.

Measuring at TP-2 the voltage varies from 16 mV to .443V when adjusting the CAR control in both FSK and CW mode. On Conn IF-5 at the CV terminal, the voltage varies from .12V to 8.95V in both FSK and CW mode when adjusting the CAR control.

Also, on the FIX VOX board FIX3-11 is grounded with no key plugged in. Plugging a key in, FIX3-11 follows the key (open key up, grounded key down).

I have cleaned the contacts on the Mode switch and checked for broken wires.

At TP-5 I measure 8.831434 MHz at .64V P-P (on scope) in all positions of the mode switch without the Send switch flipped. When I flip the Send switch the voltage drops to .48V P-P. The CAR control has no affect on the signal level with the Send switch in either position.

I measure 8.97V at the CW terminal on CAR-2 when I flip the Send switch. I measure 8.94V at the anode of D1 and 8.19V at the cathode when the Send switch is flipped.

I have a couple of multimeters, a 150 MHz analog scope, 100 MHz digital scope, W7ZOI power meter, and a KA7EXM power meter. I feel comfortable taking measurements anywhere inside the radio including the Final Cage.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

For some reason I cannot read your entire response? It appears you are reporting back that you have good bias voltage available at the BM from the Car Pot. In CW TX mode you need this bias voltage and you need the local oscillator (LO) or Carrier to produce an output. Which in this case it is 8.830.70mhz CA-2 produced on the CAR-2 Unit.

You are getting CA-2 Carrier in FSK mode so it tells me the Crystal and the soldering at its pins have to be good.

If you have a RF millivolt meter or O-scope you can measure the 8830.7 mhz Carrier at the IF board at TP-5.TP-5 is tucked back in the corner under the chassis side rail. With rig in CW mode flip to send and measure the level and the frequency at TP-5. It should be approx 300mv rms or approx 850mv P-P on a scope at 8830.70mhz.

1. In LSB/USB should be 60ma resting plate current when you flip to send or key the mic. No indication on RF meter position until you modulate the rig (speak in mic). Can you see and adjust the resting plate current in SSB mode?

2. In Tune/CW will be plate current when you have RF drive (Car Pot advanced) only if you have RF drive as indicated by peaking the ALC indication with the Drive control.

Are you certain that Aux and TR relays are keying when you flip to send or key the mic? Sounds like they are based on seeing tube voltage dropping. Bias voltage at Finals control grid better not be dropping only 10%. It should change from approx -100vdc cutoff bias to approx -55vdc operating bias. If not then plate current and no RF output.

3. You can try a new 12BY7A as easy to do, but your rig has the diagnostic meter you need. Turn off SG switch and place rig in CW mode and peak the ALC indication by advancing the Car pot. Should be able to get full scale meter deflection (FSD) and hold there a few seconds on each band without the ALC indication falling off. Should get FSD with Car Pot advanced no more than approx 1000 to 1100. Rest between each band test as Driver tube is running class A (full plate current).

4 If RF detector is pegging at 70ma plate current then turn down the sensitivity pot. You always have to adjust the sensitivity pot. Set it for approx 2/3 deflection at 100 watts out. Would have been handy if KW would have put the pot on the front panel. They provided this meter position as it is better to load a Class AB1 linear amp by tuning for max rf output without exceeding plate dissipation than using the old dip and load method. They also provided it as external wattmeters were not common and they wanted the radio to be instrumented to be stand alone.

5. I would not use a 50 watt dummy load. If you must then have to realize all dummy loads have a duty cycle. Can use it but have to limit key down time.

6. When you get a couple of bucks ahead suggest you get an external wattmeter. Makes a good Loading aid and a good diagnostic tool. Drake W4, Heath HM-102, any of the MFJs are good and give you a SWR bridge and Wattmeter in one piece of test gear. Having actual output wattage tells you a lot more than looking at relative RF output power by measuring rf voltage at SO-239 or measuring the temperature of your dummy load.

I have a Kenwood TS-820S. Receive is working fine. Strange transmit problem.

When the Mode switch is the Tune, CW, USB, or LSB postion and I operate the Send switch I get no plate current and no output. When the switch is in the FSK position, I get almost normal plate current and can tune the rig to about 3/4 full power out. I can only get the load and plate controls to 160 ma into my dummy load with carrier control at max. Maybe a bad 12BY7 preventing full power out.

The other strange thing is when the meter switch is in the RF position, I can only increase the carrier control to about 70 ma plate current before the meter pegs when in FSK mode.

My 50 watt dummy load doesn't have a power indicator but I know the transmitter is putting out decent power in FSK mode as the resistors in the dummy load are getting warm.

Voltages (SG, Plate, Bias) are all normal. They drop about 10% when switching from receive to transmit mode. This drop happens in all postions of the mode switch, not just the FSK mode.

This makes no sense as in most cases the Tune and CW contacts of S6 are tied together. And S6-2 ties Tune, CW, and FSK together. Has anyone seen this issue before or give me an idea where to look for the problem?

Hi Group,

I have a SP-520 for sale, hate for it just to sit around and collect dust here, as it does not fit on the shack desk any more after adding my vintage AM station last year to the desk line up. If any one is looking for one to complete their station looking to get $60.00 delivered. Would ship by USPS well packed.

If you need photos, please contact me direct at Stg57@yahoo.com not to tie up bandwidth.

Terry,

I read a little over 700mV at the drain of Q18 (actually the backside of C92 feeding the coax). I think you meant Q18 instead of Q10.

D7 and D8 are the CW switching diodes. With the mode switch in CW position, I have 2.98 volts on the anode of D7 and 2.34 volts on the cathode. I have 10.0 volts on the anode of D8 and 9.40 volts on the cathode. These voltages are there in both RX and TX, just a few 10ths of a volt lower in TX mode.

Can you confirm how the 3 pin cable ofr IF2 is supposed to plug in? It only has 3 wires but there are 5 pins on the IF board at that point. According to the chassis wiring diagram, only the first 3 pins are used as they come from S6-1.

I don't think there is anything wrong with the CW filter and the switching diodes as the CW filter works fine in RX mode.

I have 400mV P-P on Gate 1 of Q1 instead of the 160mV when flipping Send. I also have 2400mV P-P on the drain instead of 1000mV when flipping Send.

TIF signal on Conn IF-3 is 400mV P-P and the sine wave isn't quiet as clean there as it is on the drain of Q1.

Hopefully we are making progress.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Good job. Much better.

If I understand your chart you are telling me that you have approx 640mv P-P @ 8.83077 at TP-5 in CW mode with rig flipped to Send (heaters off and SG switch off). 900mv P-P is attainable by adjusting T1 on CAR-2 board, but can do later unless you want to peak it now. 640mv will work for testing.

If this is true then you have confirmed that you have the two things you need at the Balanced Mod to produce RF output from it in CW mode. 1. Offset bias voltage and 2. Proper Carrier freq and level.

From the BM output the CW signal is routed to the Crystal IF Filter and then to Q1 the Transmit IF Amp or TIF amp. TIF signal leaves the IF board and is routed to the RF board to the TX Mixer where it is mixed with VCO to produce the actual transmit rf drive signal. No TIF signal and there will be no RF drive and no RF output. Also no VCO or low VCO level and no rf drive. Lets validate that we have TIF signal in CW mode first.

Unfortunately KW didnt provide a nice test point at the output of the Balanced Mod to measure the DSBSC signal in SSB mode or the Carrier in CW mode. However, you can get on the Drain of Q10 with a hat pin or floral arrangement pin and mini-grabber test lead. If you locate the BM ring diodes D26-D29 and then output Xfmr T10 you will see Q10. It is a metal can dual gate mosfet. Looking down on the can the Drain is the upper right lead. You should read approx 800mv P-P here. This signal is routed to the Xtal filter thru switcing diodes.

Do you have the CW filter installed. It is rare but could have a bad filter. More common to have a bad switching diode.

After signal passes thru the Xtal filter it is applied to Gate 1 of TIF amp Q1. It is also a metal can dual gate mosfet and sits outside and almost between the two filters at the inboard end. Looking down on Q1 Gate 1 is at 1200. Should have approx 160mv P-P here. The Drain is at 0600 and should have approx 1000mv P-P. TIF output is on Conn IF-3 Pin 2 and should have approx 850mv P-P here. You can jump right to measuring TIF output if you want and if good then off to the RF board.

We know that you have TIF output in FSK mode as you reported good RF output in that mode. I dont kow if you keyed rig in FSK and noted the 170hz shift or not, but not important right now. Also, you should have noted that the RF output in FSK is lower as the 820 lowers the Finals Screen Grid voltage in FSK mode so the tubes plate dissipation is not exceeded in this high duty cycle mode.

That should be enough for now.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

This is what I am seeing:
TP-5 and CJ3-CA2 have the same levels in CW and FSK modes: 820mV P-P in RX mode. Flipping Send switch the level drops to 640mV P-P. I have a Tektronix 2445 Scope and have the probe in 10X to prevent loading the circuit.

Frequencies measured at CJ3-CA2:
RX mode FSK - 8.828414 - TX mode FSK 8.830620
RX mode LSB - 8.828414 - TX mode LSB 8.828579
RX mode USB - 8.831460 - TX mode USB 8.831625
RX mode CW - 8.831460 - TX mode CW 8.830777

Frequencies measured at TP-5:
RX mode FSK - 8.828410 - TX mode FSK 8.830616
RX mode LSB - 8.828410 - TX mode LSB 8.828575
RX mode USB - 8.831450 - TX mode USB 8.831622
RX mode CW - 8.831446 - TX mode CW 8.830773

I am using a Simpson 710 Frequency counter. Specs say 1 Meg input shunted by 30 pF. The slight differences in frequency readings between CJ3-CA2 and TP-5 is probably due to the cable capacitance of the cable between IF5-13 and CJ3-CA2.

I have been taking all of these measurements with the SG switch turned off and the heater switch turned off.

Ray:

I mis-spoke in Item 2 when I said you cant measure carrier at TP-5 in Rx in any of the mode switch positions. There will be legitimate carrier but not of interest.

There will be Carrier at CA-2 and TP-5 in Rx in all positions of the mode switch that you should see, but it is meaningless for CW Tx operation. It was not correct for me to label it as "Leakage" signals.

It is there by design but not for Rx or Tx operation. CA-1 Carrier Osc signals are coupled to the CAR-2 board to amp Q3 and then on to TP-5 at IF board and then sampled and sent to the CCR lead to provide carrier oscillator signals for the Counter Mixer Board. So the carrier osc signals you were measuring at each position of the mode switch in Rx are there by design to feed the counter, but of no interest to us as not utilized for the BM and CW transmit.

So you will see approx 250mv rms at 8831.50 mhz in CW and LSB and 250mv at 8828.5mhz in LSB and FSK, but not used by the BM. BM is not used in Rx operation. So disregard these signal other than the low levels you measured cannot be correct if your counter is working properly. I suspect you are not using O-scope properly. Are you using a 10X probe?

What I meant to say is at CA-2 and TP-5 the only frequency and level we care about is in CW and FSK positions of the mode switch in Tx. CA-2 carrier oscillator should be approx 250mv rms @ 8830.70mhz when in CW and FSK mode when flipped to send. This is what you are trying to validate. Measure at TP-5 in FSK as you know it is working. So use it to get your O-scope set up correctly and you can see approx 850mv P-P at 8830.7mhz. Once you can read that on your O-scope now switch to CW mode and flip to send to measure carrier osc signal level at TP-5.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Yes this new format gives me problems as well.

1. You are getting proper dc bias voltage to the BM. You need to confirm you are getting the Carrier Osc signal.

2. You cannot measure any Carrier freq or level at TP-5 in RX for any position of the mode switch. You may read some leakage signals in RX mode but meaningless. The BM is only used for TX and not RX. Only time you can measure any meaningful Carrier Osc frequency or level at TP-5 is in TX with the mode switch in CW or FSK. Carrier in RX mode is applied to another Mixer called the Product Detector and it arrives at IF board on IF-4 C1A terminal. You have separate Carrier Oscillators for RX and TX.

Also, the Car Level Pot has nothing to do with the Carrier Osc levels produced on the CAR Assembly Unit. The Car level pot unbalances the balanced modulator and determines the carrier output level from the BM.

You really need to measure CA-2 produced on the CAR-2 board. If you do not have 300mv of 8830.7mhz at TP-5 in CW mode when you flip to Send then you have to work your way back from TP-5 to CAR-2 board. CA2 can be checked on the 7th terminal up on the white terminal block

on the CAR-2 board. On the IF board it comes in on Conn IF-5 pin 13.

At this point you have not confirmed that you have CAR-2 Q1 Oscillator running and available.

3. The DC voltages that you measured at D1 prove that you are getting the turn on voltages for Buffer amp Q2 so if Q1 is oscillating should get CW TX Carrier at CJ-3 and on to the IF board if all connectors are good.

You may have to adjust the frequency and output level but can talk about that later.

Suggest you buy a Freq Counter. Can measure Freq roughly with O-scope. Some measure and display Freq (may or may not do so accurately) and some require using F=1/T and not accurate enough for adjusting the Oscillators in the KW hybrids.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Let's try this again. For some reason yahoo has been mangling my posts. This has been a problem ever since they went to this new stupid format they are using.

Measuring at TP-2 the voltage varies from 16 mV to .443V when adjusting the CAR control in both FSK and CW mode. On Conn IF-5 at the CV terminal, the voltage varies from .12V to 8.95V in both FSK and CW mode when adjusting the CAR control.

Also, on the FIX VOX board FIX3-11 is grounded with no key plugged in. Plugging a key in, FIX3-11 follows the key (open key up, grounded key down).

I have cleaned the contacts on the Mode switch and checked for broken wires.

At TP-5 I measure 8.831434 MHz at .64V P-P (on scope) in all positions of the mode switch without the Send switch flipped. When I flip the Send switch the voltage drops to .48V P-P. The CAR control has no affect on the signal level with the Send switch in either position.

I measure 8.97V at the CW terminal on CAR-2 when I flip the Send switch. I measure 8.94V at the anode of D1 and 8.19V at the cathode when the Send switch is flipped.

I have a couple of multimeters, a 150 MHz analog scope, 100 MHz digital scope, W7ZOI power meter, and a KA7EXM power meter. I feel comfortable taking measurements anywhere inside the radio including the Final Cage.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

For some reason I cannot read your entire response? It appears you are reporting back that you have good bias voltage available at the BM from the Car Pot. In CW TX mode you need this bias voltage and you need the local oscillator (LO) or Carrier to produce an output. Which in this case it is 8.830.70mhz CA-2 produced on the CAR-2 Unit.

You are getting CA-2 Carrier in FSK mode so it tells me the Crystal and the soldering at its pins have to be good.

If you have a RF millivolt meter or O-scope you can measure the 8830.7 mhz Carrier at the IF board at TP-5.TP-5 is tucked back in the corner under the chassis side rail. With rig in CW mode flip to send and measure the level and the frequency at TP-5. It should be approx 300mv rms or approx 850mv P-P on a scope at 8830.70mhz.

I would measure the level first before you look at it with a Freq Counter as the counter may pull the level down. If you dont have a means to measure CA-2 Carrier level and frequency then at minimum measure CW terminal at CAR-2 Unit board to make sure you are getting CW TX bias voltage.

If you remove the 2 screws that secure the cover you will see a white 10 pin connector. The 3rd pin from the Crystal is the CW terminal. When you flip to send in CW mode should see approx 9.0vdc here. If you have 9vdc and still no output then suspect bad switching diode D1. D1 is close to the Crystal and you can measure the voltage at its anode and cathode. When you flip to send in CW mode should read approx 9vdc on the anode and approx 8.3vdc on the cathode. Note: The 9vdc will depend on where the AVR regulated 9vdc has been set too.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

On Conn IF-5 CV the voltage varies from .1 volts to 8.95 volts as I rotate the CAR control. On TP-2 the voltage varies from 16 mV to .443 volts as I rotate the CAR control. These voltages are the same with the Mode switch in either CW or FSK mode.

Also, on the FIX VOX board, FIX3-11 is shorted to ground when the key is not plugged in. If I plug the key in, FIX3-11 follows the key, open with key up, ground with key down. I cleaned the mode switch and visually checked it for broken wires.

I have a couple of multimeters, a 150 MHz analog scope, a 100 MHz digital scope, a W7ZOI power meter, and a KA7EXM power meter. I feel comportable taking measurements anywhere inside the rig, including the final cage.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray

I forgot to mention where I am going with this (if not obvious) is a bad/dirty Mode switch contact or a broken wire at the mode switch in CW mode. The fact that you have output in FSK tells me that you do have approx 0.0 to 0.60vdc at TP-2 which then means the path from CV to the BM is good.

If you have no DMM, VOM, or VTVM the mode switch in a TS820 is an open deck type and pretty accessible with bottom cover off so you should be able to apply some deoxit and canned air to clean the contacts.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK well that would have been a quick fix and not first time so had to ask.

What test gear do you have and what is your comfort level to take measurements inside the rig?

When you inject audio into mic line and get output it tells you that your Balanced Modulator is working. In CW mode to produce output from the BM the Car Pot provides variable DC voltage to bias on the ring diodes. It is derives this bias voltage from regulated 9vdc from AVR board thru mode switch contacts.

The BM is on the IF board. Need to measure at Conn IF-5 at the CV terminal. Should see variable 0 to 9vdc at CV as you adjust the Car Pot thru its range.

Then measure at TP-2 and should see approx 0.0 to 0.70vdc as you adjust the Car Pot.

Ray:

Do you have a key in the key jack? If so remove it or key the key with Car Pot advanced. Cant load rig in CW mode if you have a key in key jack and it isnt closed. Brings back memories of the J-38 slider bar.

We can talk about plate dip not occurring at right place when we get CW working.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

Thanks for the comments.

1) I have 60 ma of current when I flip Send switch in CW, USB, and LSB modes. I don't have a microphone as I only operated CW back when I was on the air. I have a 1KHz tone generator and connected it to the microphone input. When I do this and increase MIC control in both USB and LSB I am able to drive plate current to the same 160 ma (on 20 meters) that I get in the FSK mode. So it appears CW is the only mode that isn't functioning.

2) I tuned the rig to the max power out (IP 160 ma) into the dummy load in the FSK position. I then switch to CW mode but the IP stays at 60 ma. This is with the CAR control at max (10 mark). Bias voltage drops from -100 to -63 volts when I flip Send switch in CW mode.

3) In the FSK mode I get almost FSD with CAR control at max on 20 meters in the ALC position. I am only 2 tick marks away from FSD. On 80, 40, and 160 I am able to get FSD at lower levels of the CAR control. However, when I turn SG back on and tune, the plate dip is in the wrong position for 40 and 160. For both of those bands max dip is at the very low

end of 3.5 dial marking. On 20, 15, and 10 the dip is in the correct position. On 10 I am only able to get 80 ma of plate current at min dip with CAR at max. This does indicate the 12BY7 is bad. I think I have a spare one somewhere around here - just have to look. When I switch to USB or LSB I am able to get the same levels of ALC deflection as FSK when I inject the 1 KHz. However, in CW mode I do not get any ALC meter deflection.

4) I will perform this step once the rig is working.

5) I am using the dummy load because I have a 40 meter dipole 8 feet off the ground (HOA) as my only antenna and not sure of the impedance it reflects. I have a Heath HM-15 SWR bridge but it doesn't have a watts reading. I just received an order from Mouser yesterday with the parts to build the dummy load that is on the K4EAA website. I am including the power measurement components so I will be able to know what my power out is. Once I am back on the air I will obtain an inline watt meter.

6) I haven't been on the air in 17 years and am wanting to get back on since I will be retiring in Jan and moving to somewhere that doesn't have a HOA. I have a HW-100 and a FT-101E that have sat in the garage for the last 17 years. I built the HW-100 back in 1968 and last used it in 1986. The FT-101 was working and I was using it on a daily basis when I went QRT at the end 1996. I bought this TS-820 10 years ago but have never used it. It has sat in the closet in my office since I bought it. I figured I would try to get it working first as it hasn't been exposed to extreme temperatures. I would be scared to power the other two up without replacing all the power supply caps first. My garage never drops below 100 four months out of the year.

Ray:

Sorry about Q10 vs Q18. My fingers work better than what is left of my brain.

The 3 conductor plug should be positioned in forward position toward the front panel.

One thing we did not talk about is whereiyou should have the Car Level Pot set to take these measurements.

The TX Level Diagram is shown in the Service Manual. These levels were taken by Kenwood by loading the rig to approx 100 watts out at 14.175mhz and then turn the SG switch off and leave Car pot alone and Drive control alone.

Since you have no RF output in CW mode I suggest you do this for remainder of the readings:

1. VFO 14.175
2. Peak the Drive Control on receiver noise or the marker signal
3. Car Level Pot 1200
4. Heater on
5. SG switch off
6. Flip to Send to take RF drive levels

So the differences in voltages may be due to where we each have our Car Level pot set at.

Suggest you measure the voltage and frequency of the TIF signal at IF-3 Pin 2 one more time and it should be approx 250mv rms or 700mv P-P @ 8830.7mhz.

If you have close to this time to move on to the RF board. I must say this is getting a little odd as you have good output ini SSB and FSK which tells us you have good TIF level and the TX Mixer on RF Board is working which means you have good VCO (LO to the mixer).

Are you 100% certain you have no CW RF output on all bands? If so, then proceed on to the RF board with Heaters On and SG off and rig peaked as noted above.

You should have close to the values noted on the TX Level Diagram. At Conn RF-1 Pin 10 the 8.830 TIF signal level is approx 38mv rms or 108 P-P.

At output of TX Mixer should have approx 1.5v rms or 4.2v P-P rf drive at MD. At MD frequency will now be 14.175mhz transmit frequency.

If you have no RF drive or very weak at MD then need to measure the VCO level and frequency at RF-1 pin 4 and on board at TP-1. Should be close to 1.0v rms level. If no VCO try on other bands.

We are making good progress. Your Tek 2445 is perfect scope for KW Hybrid work and you apparently know how to use it and can read a schematic and can locate points on these high density boards to take measurements. This really helps.

Based on your report of no RF output in CW mode I would have thought we would have found no TIF sig at output of the IF board. TIF is not band specific and often is caused by no output from the Bal Modulator, This is why I had you start by testing for bias voltage and LO signal available. Never expected that we would be at the RF board and TX Mixer based on good RF output on other modes.

Terry,

I read a little over 700mV at the drain of Q18 (actually the backside of C92 feeding the coax). I think you meant Q18 instead of Q10.

D7 and D8 are the CW switching diodes. With the mode switch in CW position, I have 2.98 volts on the anode of D7 and 2.34 volts on the cathode. I have 10.0 volts on the anode of D8 and 9.40 volts on the cathode. These voltages are there in both RX and TX, just a few 10ths of a volt lower in TX mode.

Can you confirm how the 3 pin cable ofr IF2 is supposed to plug in? It only has 3 wires but there are 5 pins on the IF board at that point. According to the chassis wiring diagram, only the first 3 pins are used as they come from S6-1.

I don't think there is anything wrong with the CW filter and the switching diodes as the CW filter works fine in RX mode.

I have 400mV P-P on Gate 1 of Q1 instead of the 160mV when flipping Send. I also have 2400mV P-P on the drain instead of 1000mV when flipping Send.

TIF signal on Conn IF-3 is 400mV P-P and the sine wave isn't quiet as clean there as it is on the drain of Q1.

Hopefully we are making progress.

Ray:

Good job. Much better.

If I understand your chart you are telling me that you have approx 640mv P-P @ 8.83077 at TP-5 in CW mode with rig flipped to Send (heaters off and SG switch off). 900mv P-P is attainable by adjusting T1 on CAR-2 board, but can do later unless you want to peak it now. 640mv will work for testing.

If this is true then you have confirmed that you have the two things you need at the Balanced Mod to produce RF output from it in CW mode. 1. Offset bias voltage and 2. Proper Carrier freq and level.

From the BM output the CW signal is routed to the Crystal IF Filter and then to Q1 the Transmit IF Amp or TIF amp. TIF signal leaves the IF board and is routed to the RF board to the TX Mixer where it is mixed with VCO to produce the actual transmit rf drive signal. No

TIF signal and there will be no RF drive and no RF output. Also no VCO or low VCO level and no rf drive. Lets validate that we have TIF signal in CW mode first.

Unfortunately KW didnt provide a nice test point at the output of the Balanced Mod to measure the DSBSC signal in SSB mode or the Carrier in CW mode. However, you can get on the Drain of Q10 with a hat pin or floral arrangement pin and mini-grabber test lead. If you locate the BM ring diodes D26-D29 and then output Xfmr T10 you will see Q10. It is a metal can dual gate mosfet. Looking down on the can the Drain is the upper right lead. You should read approx 800mv P-P here. This signal is routed to the Xtal filter thru switcing diodes.

Do you have the CW filter installed. It is rare but could have a bad filter. More common to have a bad switching diode.

After signal passes thru the Xtal filter it is applied to Gate 1 of TIF amp Q1. It is also a metal can dual gate mosfet and sits outside and almost between the two filters at the inboard end. Looking down on Q1 Gate 1 is at 1200. Should have approx 160mv P-P here. The Drain is at 0600 and should have approx 1000mv P-P. TIF output is on Conn IF-3 Pin 2 and should have approx 850mv P-P here. You can jump right to measuring TIF output if you want and if good then off to the RF board.

We know that you have TIF output in FSK mode as you reported good RF output in that mode. I dont kow if you keyed rig in FSK and noted the 170hz shift or not, but not important right now. Also, you should have noted that the RF output in FSK is lower as the 820 lowers the Finals Screen Grid voltage in FSK mode so the tubes plate dissipation is not exceeded in this high duty cycle mode.

That should be enough for now.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

This is what I am seeing:
TP-5 and CJ3-CA2 have the same levels in CW and FSK modes: 820mV P-P in RX mode. Flipping Send switch the level drops to 640mV P-P. I have a Tektronix 2445 Scope and have the probe in 10X to prevent loading the circuit.

Frequencies measured at CJ3-CA2:
RX mode FSK - 8.828414 - TX mode FSK 8.830620
RX mode LSB - 8.828414 - TX mode LSB 8.828579
RX mode USB - 8.831460 - TX mode USB 8.831625
RX mode CW - 8.831460 - TX mode CW 8.830777

Frequencies measured at TP-5:
RX mode FSK - 8.828410 - TX mode FSK 8.830616
RX mode LSB - 8.828410 - TX mode LSB 8.828575
RX mode USB - 8.831450 - TX mode USB 8.831622
RX mode CW - 8.831446 - TX mode CW 8.830773

I am using a Simpson 710 Frequency counter. Specs say 1 Meg input shunted by 30 pF. The slight differences in frequency readings between CJ3-CA2 and TP-5 is probably due to the cable capacitance of the cable between IF5-13 and CJ3-CA2.

I have been taking all of these measurements with the SG switch turned off and the heater switch turned off.

Ray:

I mis-spoke in Item 2 when I said you cant measure carrier at TP-5 in Rx in any of the mode switch positions. There will be legitimate carrier but not of interest.

There will be Carrier at CA-2 and TP-5 in Rx in all positions of the mode switch that you should see, but it is meaningless for CW Tx operation. It was not correct for me to label it as "Leakage" signals.

It is there by design but not for Rx or Tx operation. CA-1 Carrier Osc signals are coupled to the CAR-2 board to amp Q3 and then on to TP-5 at IF board and then sampled and sent to the CCR lead to provide carrier oscillator signals for the Counter Mixer Board. So the carrier osc signals you were measuring at each position of the mode switch in Rx are there by design to feed the counter, but of no interest to us as not utilized for the BM and CW transmit.

So you will see approx 250mv rms at 8831.50 mhz in CW and LSB and 250mv at 8828.5mhz in LSB and FSK, but not used by the BM. BM is not used in Rx operation. So disregard these signal other than the low levels you measured cannot be correct if your counter is working properly. I suspect you are not using O-scope properly. Are you using a 10X probe?

What I meant to say is at CA-2 and TP-5 the only frequency and level we care about is in CW and FSK positions of the mode switch in Tx. CA-2 carrier oscillator should be approx 250mv rms @ 8830.70mhz when in CW and FSK mode when flipped to send. This is what you are trying to validate. Measure at TP-5 in FSK as you know it is working. So use it to get your O-scope set up correctly and you can see approx 850mv P-P at 8830.7mhz. Once you can read that on your O-scope now switch to CW mode and flip to send to measure carrier osc signal level at TP-5.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Yes this new format gives me problems as well.

1. You are getting proper dc bias voltage to the BM. You need to confirm you are getting the Carrier Osc signal.

2. You cannot measure any Carrier freq or level at TP-5 in RX for any position of the mode switch. You may read some leakage signals in RX mode but meaningless. The BM is only used for TX and not RX. Only time you can measure any meaningful Carrier Osc frequency or level at TP-5 is in TX with the mode switch in CW or FSK. Carrier in RX mode is applied to another Mixer called the Product Detector and it arrives at IF board on IF-4 C1A terminal. You have separate Carrier Oscillators for RX and TX.

Also, the Car Level Pot has nothing to do with the Carrier Osc levels produced on the CAR Assembly Unit. The Car level pot unbalances the balanced modulator and determines the carrier output level from the BM.

You really need to measure CA-2 produced on the CAR-2 board. If you do not have 300mv of 8830.7mhz at TP-5 in CW mode when you flip to Send then you have to work your way back from TP-5 to CAR-2 board. CA2 can be checked on the 7th terminal up on the white terminal block on the CAR-2 board. On the IF board it comes in on Conn IF-5 pin 13.

At this point you have not confirmed that you have CAR-2 Q1 Oscillator running and available.

3. The DC voltages that you measured at D1 prove that you are getting the turn on voltages for Buffer amp Q2 so if Q1 is oscillating should get CW TX Carrier at CJ-3 and on to the IF board if all connectors are good.

You may have to adjust the frequency and output level but can talk about that later.

Suggest you buy a Freq Counter. Can measure Freq roughly with O-scope. Some measure and display Freq (may or may not do so accurately) and some require using F=1/T and not accurate enough for adjusting the Oscillators in the KW hybrids.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Let's try this again. For some reason yahoo has been mangling my posts. This has been a problem ever since they went to this new stupid format they are using.

Measuring at TP-2 the voltage varies from 16 mV to .443V when adjusting the CAR control in both FSK and CW mode. On Conn IF-5 at the CV terminal, the voltage varies from .12V to 8.95V in both FSK and CW mode when adjusting the CAR control.

Also, on the FIX VOX board FIX3-11 is grounded with no key plugged in. Plugging a key in, FIX3-11 follows the key (open key up, grounded key down).

I have cleaned the contacts on the Mode switch and checked for broken wires.

At TP-5 I measure 8.831434 MHz at .64V P-P (on scope) in all positions of the mode switch without the Send switch flipped. When I flip the Send switch the voltage drops to .48V P-P. The CAR control has no affect on the signal level with the Send switch in either position.

I measure 8.97V at the CW terminal on CAR-2 when I flip the Send switch. I measure 8.94V at the anode of D1 and 8.19V at the cathode when the Send switch is flipped.

I have a couple of multimeters, a 150 MHz analog scope, 100 MHz digital scope, W7ZOI power meter, and a KA7EXM power meter. I feel comfortable taking measurements anywhere inside the radio including the Final Cage.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

For some reason I cannot read your entire response? It appears you are reporting back that you have good bias voltage available at the BM from the Car Pot. In CW TX mode you need this bias voltage and you need the local oscillator (LO) or Carrier to produce an output. Which in this case it is 8.830.70mhz CA-2 produced on the CAR-2 Unit.

You are getting CA-2 Carrier in FSK mode so it tells me the Crystal and the soldering at its pins have to be good.

If you have a RF millivolt meter or O-scope you can measure the 8830.7 mhz Carrier at the IF board at TP-5.TP-5 is tucked back in the corner under the chassis side rail. With rig in CW mode flip to send and measure the level and the frequency at TP-5. It should be approx 300mv rms or approx 850mv P-P on a scope at 8830.70mhz.

I would measure the level first before you look at it with a Freq Counter as the counter may pull the level down. If you dont have a means to measure CA-2 Carrier level and frequency then at minimum measure CW terminal at CAR-2 Unit board to make sure you are getting CW TX bias voltage.

If you remove the 2 screws that secure the cover you will see a white 10 pin connector. The 3rd pin from the Crystal is the CW terminal. When you flip to send in CW mode should see approx 9.0vdc here. If you have 9vdc and still no output then suspect bad switching diode D1. D1 is close to the Crystal and you can measure the voltage at its anode and cathode. When you flip to send in CW mode should read approx 9vdc on the anode and approx 8.3vdc on the cathode. Note: The 9vdc will depend on where the AVR regulated 9vdc has been set too.

I forgot to mention where I am going with this (if not obvious) is a bad/dirty Mode switch contact or a broken wire at the mode switch in CW mode. The fact that you have output in FSK tells me that you do have approx 0.0 to 0.60vdc at TP-2 which then means the path from CV to the BM is good.

If you have no DMM, VOM, or VTVM the mode switch in a TS820 is an open deck type and pretty accessible with bottom cover off so you should be able to apply some deoxit and canned air to clean the contacts.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK well that would have been a quick fix and not first time so had to ask.

What test gear do you have and what is your comfort level to take measurements inside the rig?

When you inject audio into mic line and get output it tells you that your Balanced Modulator is working. In CW mode to produce output from the BM the Car Pot provides variable DC voltage to bias on the ring diodes. It is derives this bias voltage from regulated 9vdc from AVR board thru mode switch contacts.

The BM is on the IF board. Need to measure at Conn IF-5 at the CV terminal. Should see variable 0 to 9vdc at CV as you adjust the Car Pot thru its range.

Then measure at TP-2 and should see approx 0.0 to 0.70vdc as you adjust the Car Pot.

Ray:

Do you have a key in the key jack? If so remove it or key the key with Car Pot advanced. Cant load rig in CW mode if you have a key in key jack and it isnt closed. Brings back memories of the J-38 slider bar.

We can talk about plate dip not occurring at right place when we get CW working.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

Thanks for the comments.

1) I have 60 ma of current when I flip Send switch in CW, USB, and LSB modes. I don't have a microphone as I only operated CW back when I was on the air. I have a 1KHz tone generator and connected it to the microphone input. When I do this and increase MIC control in both USB and LSB I am able to drive plate current to the same 160 ma (on 20 meters) that I get in the FSK mode. So it appears CW is the only mode that isn't functioning.

2) I tuned the rig to the max power out (IP 160 ma) into the dummy load in the FSK position. I then switch to CW mode but the IP stays at 60 ma. This is with the CAR control at max (10 mark). Bias voltage drops from -100 to -63 volts when I flip Send switch in CW mode.

3) In the FSK mode I get almost FSD with CAR control at max on 20 meters in the ALC position. I am only 2 tick marks away from FSD. On 80, 40, and 160 I am able to get FSD at lower levels of the CAR control. However, when I turn SG back on and tune, the plate dip is

in the wrong position for 40 and 160. For both of those bands max dip is at the very low end of 3.5 dial marking. On 20, 15, and 10 the dip is in the correct position. On 10 I am only able to get 80 ma of plate current at min dip with CAR at max. This does indicate the 12BY7 is bad. I think I have a spare one somewhere around here - just have to look. When I switch to USB or LSB I am able to get the same levels of ALC deflection as FSK when I inject the 1 KHz. However, in CW mode I do not get any ALC meter deflection.

4) I will perform this step once the rig is working.

5) I am using the dummy load because I have a 40 meter dipole 8 feet off the ground (HOA) as my only antenna and not sure of the impedance it reflects. I have a Heath HM-15 SWR bridge but it doesn't have a watts reading. I just received an order from Mouser yesterday with the parts to build the dummy load that is on the K4EAA website. I am including the power measurement components so I will be able to know what my power out is. Once I am back on the air I will obtain an inline watt meter.

6) I haven't been on the air in 17 years and am wanting to get back on since I will be retiring in Jan and moving to somewhere that doesn't have a HOA. I have a HW-100 and a FT-101E that have sat in the garage for the last 17 years. I built the HW-100 back in 1968 and last used it in 1986. The FT-101 was working and I was using it on a daily basis when I went QRT at the end 1996. I bought this TS-820 10 years ago but have never used it. It has sat in the closet in my office since I bought it. I figured I would try to get it working first as it hasn't been exposed to extreme temperatures. I would be scared to power the other two up without replacing all the power supply caps first. My garage never drops below 100 four months out of the year.

AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

1. In LSB/USB should be 60ma resting plate current when you flip to send or key the mic. No indication on RF meter position until you modulate the rig (speak in mic). Can you see and adjust the resting plate current in SSB mode?

2. In Tune/CW will be plate current when you have RF drive (Car Pot advanced) only if you have RF drive as indicated by peaking the ALC indication with the Drive control.

Are you certain that Aux and TR relays are keying when you flip to send or key the mic? Sounds like they are based on seeing tube voltage dropping. Bias voltage at Finals control grid better not be dropping only 10%. It should change from approx -100vdc cutoff bias to approx -55vdc operating bias. If not then plate current and no RF output.

3. You can try a new 12BY7A as easy to do, but your rig has the diagnostic meter you need. Turn off SG switch and place rig in CW mode and peak the ALC indication by advancing the Car pot. Should be able to get full scale meter deflection (FSD) and hold there a few seconds on each band without the ALC indication falling off. Should get FSD with Car Pot advanced no more than approx 1000 to 1100. Rest between each band test as Driver tube is running class A (full plate current).

4 If RF detector is pegging at 70ma plate current then turn down the sensitivity pot. You always have to adjust the sensitivity pot. Set it for approx 2/3 deflection at 100 watts out. Would have been handy if KW would have put the pot on the front panel. They provided this meter position as it is better to load a Class AB1 linear amp by tuning for max rf

output without exceeding plate dissipation than using the old dip and load method. They also provided it as external wattmeters were not common and they wanted the radio to be instrumented to be stand alone.

5. I would not use a 50 watt dummy load. If you must then have to realize all dummy loads have a duty cycle. Can use it but have to limit key down time.

6. When you get a couple of bucks ahead suggest you get an external wattmeter. Makes a good Loading aid and a good diagnostic tool. Drake W4, Heath HM-102, any of the MFJs are good and give you a SWR bridge and Wattmeter in one piece of test gear. Having actual output wattage tells you a lot more than looking at relative RF output power by measuring rf voltage at SO-239 or measuring the temperature of your dummy load.

I have a Kenwood TS-820S. Receive is working fine. Strange transmit problem.

When the Mode switch is the Tune, CW, USB, or LSB postion and I operate the Send switch I get no plate current and no output. When the switch is in the FSK position, I get almost normal plate current and can tune the rig to about 3/4 full power out. I can only get the load and plate controls to 160 ma into my dummy load with carrier control at max. Maybe a bad 12BY7 preventing full power out.

The other strange thing is when the meter switch is in the RF position, I can only increase the carrier control to about 70 ma plate current before the meter pegs when in FSK mode.

My 50 watt dummy load doesn't have a power indicator but I know the transmitter is putting out decent power in FSK mode as the resistors in the dummy load are getting warm.

Voltages (SG, Plate, Bias) are all normal. They drop about 10% when switching from receive to transmit mode. This drop happens in all postions of the mode switch, not just the FSK mode.

This makes no sense as in most cases the Tune and CW contacts of S6 are tied together. And S6-2 ties Tune, CW, and FSK together. Has anyone seen this issue before or give me an idea where to look for the problem?

Ray,
AB7HE

45399. Transmitter not working - No idling current, tubes not turning on.

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)

Hello, recently acquired a TS-820. The receive works great.

However, when attempting the Tuning procedure (Checking that all controls are set according to the manual), the ALC meter did not move at the first step. I checked the Idling current and it stays at zero. Removing the cover, I checked to see if the filaments on the 6164B's light up with the H. Switch on. They do not light up.

With HV set on the meter, I do read a little over 9 on the scale.

Where are some common places that would exhibit these symptoms in the transmitter portion of the radio so that I have a starting point on what to check. Do I check if the SG switch is functional, H. Switch? External VFO cable is good. I checked that and all pins have continuity.

Any other starting bases begin troubleshooting?

Thank you!

From: Mike
Topic: 45399 Message: 45400

The HEATER switch should be set to ON after you power up the 820.

The filament voltage on the final unit's "H" pin and chassis ground
should be 12VAC with the HEATER switch ON. The final tube filaments are
wired in "series" so if one filament is open, both final tube filaments
will not light. Check the driver tube filaments, it should be lit with
the HEATER switch ON. If it is but the final tube filaments are not lit,
most likely one of the final tube filaments is OPEN.

There will be no ALC indication in TUNE mode and the IP meter indication
will remain at zero (transmitter keyed) during transmitter tune up
attempts as long as the final tube filaments are not lit even though the
HV meter (transmitter keyed) indicates 900VDC.

The SG switch should also be set to ON for normal operation BUT the SG
switch has nothing to do with the final tube filaments.

Just stay away from the plate voltage. If you don't, you may have the taste of copper pennies in your mouth.

Love the hobby as I do Enjoy, but be safe, Remember if in doubt - DON"T.

73,

Mike/K3MG

Ray:

I forgot to mention the best place to get on MD to measure the output of the TX Mixer is on the wiper of the first bandswitch deck switch on the Coil Pack board. First deck from the front panel. These are reddish brown vertical boards. Looking down on the vertical board you will see the bronze hair pin loop of the wiper at approx 1230 position. Toward right side of bandswitch shaft. Easy to touch here or clip a short mini-grabber test lead on to the window cut in the loop. You can also access MD by reaching thru VC-1 Air Variable cap chain drive and touch the foil trace, but so much easier to connect at the wiper of the bandswitch with a mini-grabber for hands free measurement. I have couple of 8 inch mini-grabber test leads that do not impact the readings very much so I use them to connect my Boonton 92E or O-scope for RF drive measurements.

On my personal TS-820S after loading to 100 watts out at 14.175mhz. With Heaters on, SG switch off and Flip to send I get the following drive levels.

1. TIF signal at Conn RF-1 Pin 10 = 120mv rms
2. MD at wiper of bandswitch deck one = 1.45v rms
3. VCO at TP-1 on RF board = 1.0v rms

Ray:

Sorry about Q10 vs Q18. My fingers work better than what is left of my brain.

The 3 conductor plug should be positioned in forward position toward the front panel.

One thing we did not talk about is whereiyou should have the Car Level Pot set to take these measurements.

The TX Level Diagram is shown in the Service Manual. These levels were taken by Kenwood by loading the rig to approx 100 watts out at 14.175mhz and then turn the SG switch off and leave Car pot alone and Drive control alone.

Since you have no RF output in CW mode I suggest you do this for remainder of the readings:

1. VFO 14.175
2. Peak the Drive Control on receiver noise or the marker signal
3. Car Level Pot 1200
4. Heater on
5. SG switch off
6. Flip to Send to take RF drive levels

So the differences in voltages may be due to where we each have our Car Level pot set at.

Suggest you measure the voltage and frequency of the TIF signal at IF-3 Pin 2 one more time and it should be approx 250mv rms or 700mv P-P @ 8830.7mhz.

If you have close to this time to move on to the RF board. I must say this is getting a little odd as you have good output ini SSB and FSK which tells us you have good TIF level and the TX Mixer on RF Board is working which means you have good VCO (LO to the mixer).

Are you 100% certain you have no CW RF output on all bands? If so, then proceed on to the RF board with Heaters On and SG off and rig peaked as noted above.

You should have close to the values noted on the TX Level Diagram. At Conn RF-1 Pin 10 the 8.830 TIF signal level is approx 38mv rms or 108 P-P.

At output of TX Mixer should have approx 1.5v rms or 4.2v P-P rf drive at MD. At MD frequency will now be 14.175mhz transmit frequency.

If you have no RF drive or very weak at MD then need to measure the VCO level and frequency at RF-1 pin 4 and on board at TP-1. Should be close to 1.0v rms level. If no VCO try on other bands.

We are making good progress. Your Tek 2445 is perfect scope for KW Hybrid work and you apparently know how to use it and can read a schematic and can locate points on these high density boards to take measurements. This really helps.

Based on your report of no RF output in CW mode I would have thought we would have found no TIF sig at output of the IF board. TIF is not band specific and often is caused by no output from the Bal Modulator, This is why I had you start by testing for bias voltage and LO signal available. Never expected that we would be at the RF board and TX Mixer based on good RF output on other modes.

Terry,

I read a little over 700mV at the drain of Q18 (actually the backside of C92 feeding the coax). I think you meant Q18 instead of Q10.

D7 and D8 are the CW switching diodes. With the mode switch in CW position, I have 2.98 volts on the anode of D7 and 2.34 volts on the cathode. I have 10.0 volts on the anode of D8 and 9.40 volts on the cathode. These voltages are there in both RX and TX, just a few 10ths of a volt lower in TX mode.

Can you confirm how the 3 pin cable ofr IF2 is supposed to plug in? It only has 3 wires but there are 5 pins on the IF board at that point. According to the chassis wiring diagram, only the first 3 pins are used as they come from S6-1.

I don't think there is anything wrong with the CW filter and the switching diodes as the CW filter works fine in RX mode.

I have 400mV P-P on Gate 1 of Q1 instead of the 160mV when flipping Send. I also have 2400mV P-P on the drain instead of 1000mV when flipping Send.

TIF signal on Conn IF-3 is 400mV P-P and the sine wave isn't quiet as clean there as it is on the drain of Q1.

Hopefully we are making progress.

Ray:

Good job. Much better.

If I understand your chart you are telling me that you have approx 640mv P-P @ 8.83077 at TP-5 in CW mode with rig flipped to Send (heaters off and SG switch off). 900mv P-P is attainable by adjusting T1 on CAR-2 board, but can do later unless you want to peak it now. 640mv will work for testing.

If this is true then you have confirmed that you have the two things you need at the Balanced Mod to produce RF output from it in CW mode. 1. Offset bias voltage and 2. Proper Carrier freq and level.

From the BM output the CW signal is routed to the Crystal IF Filter and then to Q1 the Transmit IF Amp or TIF amp. TIF signal leaves the IF board and is routed to the RF board to the TX Mixer where it is mixed with VCO to produce the actual transmit rf drive signal. No TIF signal and there will be no RF drive and no RF output. Also no VCO or low VCO level and no rf drive. Lets validate that we have TIF signal in CW mode first.

Unfortunately KW didnt provide a nice test point at the output of the Balanced Mod to measure the DSBSC signal in SSB mode or the Carrier in CW mode. However, you can get on the Drain of Q10 with a hat pin or floral arrangement pin and mini-grabber test lead. If you locate the BM ring diodes D26-D29 and then output Xfmr T10 you will see Q10. It is a metal can dual gate mosfet. Looking down on the can the Drain is the upper right lead. You should read approx 800mv P-P here. This signal is routed to the Xtal filter thru switcing diodes.

Do you have the CW filter installed. It is rare but could have a bad filter. More common to have a bad switching diode.

After signal passes thru the Xtal filter it is applied to Gate 1 of TIF amp Q1. It is also a metal can dual gate mosfet and sits outside and almost between the two filters at the inboard end. Looking down on Q1 Gate 1 is at 1200. Should have approx 160mv P-P here. The Drain is at 0600 and should have approx 1000mv P-P. TIF output is on Conn IF-3 Pin 2 and should have approx 850mv P-P here. You can jump right to measuring TIF output if you want and if good then off to the RF board.

We know that you have TIF output in FSK mode as you reported good RF output in that mode. I dont kow if you keyed rig in FSK and noted the 170hz shift or not, but not important right now. Also, you should have noted that the RF output in FSK is lower as the 820 lowers the Finals Screen Grid voltage in FSK mode so the tubes plate dissipation is not exceeded in this high duty cycle mode.

That should be enough for now.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

This is what I am seeing:
TP-5 and CJ3-CA2 have the same levels in CW and FSK modes: 820mV P-P in RX mode. Flipping Send switch the level drops to 640mV P-P. I have a Tektronix 2445 Scope and have the probe in 10X to prevent loading the circuit.

Frequencies measured at CJ3-CA2:
RX mode FSK - 8.828414 - TX mode FSK 8.830620
RX mode LSB - 8.828414 - TX mode LSB 8.828579
RX mode USB - 8.831460 - TX mode USB 8.831625
RX mode CW - 8.831460 - TX mode CW 8.830777

Frequencies measured at TP-5:
RX mode FSK - 8.828410 - TX mode FSK 8.830616
RX mode LSB - 8.828410 - TX mode LSB 8.828575
RX mode USB - 8.831450 - TX mode USB 8.831622
RX mode CW - 8.831446 - TX mode CW 8.830773

I am using a Simpson 710 Frequency counter. Specs say 1 Meg input shunted by 30 pF. The slight differences in frequency readings between CJ3-CA2 and TP-5 is probably due to the cable capacitance of the cable between IF5-13 and CJ3-CA2.

I have been taking all of these measurements with the SG switch turned off and the heater switch turned off.

Ray:

I mis-spoke in Item 2 when I said you cant measure carrier at TP-5 in Rx in any of the mode switch positions. There will be legitimate carrier but not of interest.

There will be Carrier at CA-2 and TP-5 in Rx in all positions of the mode switch that you should see, but it is meaningless for CW Tx operation. It was not correct for me to label it as "Leakage" signals.

It is there by design but not for Rx or Tx operation. CA-1 Carrier Osc signals are coupled to the CAR-2 board to amp Q3 and then on to TP-5 at IF board and then sampled and sent to the CCR lead to provide carrier oscillator signals for the Counter Mixer Board. So the carrier osc signals you were measuring at each position of the mode switch in Rx are there by design to feed the counter, but of no interest to us as not utilized for the BM and CW transmit.

So you will see approx 250mv rms at 8831.50 mhz in CW and LSB and 250mv at 8828.5mhz in LSB and FSK, but not used by the BM. BM is not used in Rx operation. So disregard these signal other than the low levels you measured cannot be correct if your counter is working properly. I suspect you are not using O-scope properly. Are you using a 10X probe?

What I meant to say is at CA-2 and TP-5 the only frequency and level we care about is in CW and FSK positions of the mode switch in Tx. CA-2 carrier oscillator should be approx 250mv rms @ 8830.70mhz when in CW and FSK mode when flipped to send. This is what you are trying

to validate. Measure at TP-5 in FSK as you know it is working. So use it to get your O-scope set up correctly and you can see approx 850mv P-P at 8830.7mhz. Once you can read that on your O-scope now switch to CW mode and flip to send to measure carrier osc signal level at TP-5.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Yes this new format gives me problems as well.

1. You are getting proper dc bias voltage to the BM. You need to confirm you are getting the Carrier Osc signal.

2. You cannot measure any Carrier freq or level at TP-5 in RX for any position of the mode switch. You may read some leakage signals in RX mode but meaningless. The BM is only used for TX and not RX. Only time you can measure any meaningful Carrier Osc frequency or level at TP-5 is in TX with the mode switch in CW or FSK. Carrier in RX mode is applied to another Mixer called the Product Detector and it arrives at IF board on IF-4 C1A terminal. You have separate Carrier Oscillators for RX and TX.

Also, the Car Level Pot has nothing to do with the Carrier Osc levels produced on the CAR Assembly Unit. The Car level pot unbalances the balanced modulator and determines the carrier output level from the BM.

You really need to measure CA-2 produced on the CAR-2 board. If you do not have 300mv of 8830.7mhz at TP-5 in CW mode when you flip to Send then you have to work your way back from TP-5 to CAR-2 board. CA2 can be checked on the 7th terminal up on the white terminal block on the CAR-2 board. On the IF board it comes in on Conn IF-5 pin 13.

At this point you have not confirmed that you have CAR-2 Q1 Oscillator running and available.

3. The DC voltages that you measured at D1 prove that you are getting the turn on voltages for Buffer amp Q2 so if Q1 is oscillating should get CW TX Carrier at CJ-3 and on to the IF board if all connectors are good.

You may have to adjust the frequency and output level but can talk about that later.

Suggest you buy a Freq Counter. Can measure Freq roughly with O-scope. Some measure and display Freq (may or may not do so accurately) and some require using F=1/T and not accurate enough for adjusting the Oscillators in the KW hybrids.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Let's try this again. For some reason yahoo has been mangling my posts. This has been a problem ever since they went to this new stupid format they are using.

Measuring at TP-2 the voltage varies from 16 mV to .443V when adjusting the CAR control in both FSK and CW mode. On Conn IF-5 at the CV terminal, the voltage varies from .12V to 8.95V in both FSK and CW mode when adjusting the CAR control.

Also, on the FIX VOX board FIX3-11 is grounded with no key plugged in. Plugging a key in, FIX3-11 follows the key (open key up, grounded key down).

I have cleaned the contacts on the Mode switch and checked for broken wires.

At TP-5 I measure 8.831434 MHz at .64V P-P (on scope) in all positions of the mode switch without the Send switch flipped. When I flip the Send switch the voltage drops to .48V P-P. The CAR control has no affect on the signal level with the Send switch in either position.

I measure 8.97V at the CW terminal on CAR-2 when I flip the Send switch. I measure 8.94V at the anode of D1 and 8.19V at the cathode when the Send switch is flipped.

I have a couple of multimeters, a 150 MHz analog scope, 100 MHz digital scope, W7ZOI power meter, and a KA7EXM power meter. I feel comfortable taking measurements anywhere inside the radio including the Final Cage.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

For some reason I cannot read your entire response? It appears you are reporting back that you have good bias voltage available at the BM from the Car Pot. In CW TX mode you need this bias voltage and you need the local oscillator (LO) or Carrier to produce an output. Which in this case it is 8.830.70mhz CA-2 produced on the CAR-2 Unit.

You are getting CA-2 Carrier in FSK mode so it tells me the Crystal and the soldering at its pins have to be good.

If you have a RF millivolt meter or O-scope you can measure the 8830.7 mhz Carrier at the IF board at TP-5.TP-5 is tucked back in the corner under the chassis side rail. With rig in CW mode flip to send and measure the level and the frequency at TP-5. It should be approx 300mv rms or approx 850mv P-P on a scope at 8830.70mhz.

I would measure the level first before you look at it with a Freq Counter as the counter may pull the level down. If you dont have a means to measure CA-2 Carrier level and frequency then at minimum measure CW terminal at CAR-2 Unit board to make sure you are getting CW TX bias voltage.

If you remove the 2 screws that secure the cover you will see a white 10 pin connector. The 3rd pin from the Crystal is the CW terminal. When you flip to send in CW mode should see approx 9.0vdc here. If you have 9vdc and still no output then suspect bad switching diode D1. D1 is close to the Crystal and you can measure the voltage at its anode and cathode. When you flip to send in CW mode should read approx 9vdc on the anode and approx 8.3vdc on the cathode. Note: The 9vdc will depend on where the AVR regulated 9vdc has been set too.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray

I forgot to mention where I am going with this (if not obvious) is a bad/dirty Mode switch contact or a broken wire at the mode switch in CW mode. The fact that you have output in FSK tells me that you do have approx 0.0 to 0.60vdc at TP-2 which then means the path from CV to the BM is good.

If you have no DMM, VOM, or VTVM the mode switch in a TS820 is an open deck type and pretty accessible with bottom cover off so you should be able to apply some deoxit and canned air to clean the contacts.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK well that would have been a quick fix and not first time so had to ask.

What test gear do you have and what is your comfort level to take measurements inside the rig?

When you inject audio into mic line and get output it tells you that your Balanced Modulator is working. In CW mode to produce output from the BM the Car Pot provides variable DC voltage to bias on the ring diodes. It is derives this bias voltage from regulated 9vdc from AVR board thru mode switch contacts.

The BM is on the IF board. Need to measure at Conn IF-5 at the CV terminal. Should see variable 0 to 9vdc at CV as you adjust the Car Pot thru its range.

Then measure at TP-2 and should see approx 0.0 to 0.70vdc as you adjust the Car Pot.

Terry,

No, I don't have a key in the key jack. However, I did plug one in and keyed it just to see if the N/C contact wasn't closing the circuit.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Do you have a key in the key jack? If so remove it or key the key with Car Pot advanced. Cant load rig in CW mode if you have a key in key jack and it isnt closed. Brings back memories of the J-38 slider bar.

We can talk about plate dip not occurring at right place when we get CW working.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

Thanks for the comments.

1) I have 60 ma of current when I flip Send switch in CW, USB, and LSB modes. I don't have a microphone as I only operated CW back when I was on the air. I have a 1KHz tone generator and connected it to the microphone input. When I do this and increase MIC control in both USB and LSB I am able to drive plate current to the same 160 ma (on 20 meters) that I get in the FSK mode. So it appears CW is the only mode that isn't functioning.

2) I tuned the rig to the max power out (IP 160 ma) into the dummy load in the FSK position. I then switch to CW mode but the IP stays at 60 ma. This is with the CAR control at max (10 mark). Bias voltage drops from -100 to -63 volts when I flip Send switch in CW mode.

3) In the FSK mode I get almost FSD with CAR control at max on 20 meters in the ALC position. I am only 2 tick marks away from FSD. On 80, 40, and 160 I am able to get FSD at lower levels of the CAR control. However, when I turn SG back on and tune, the plate dip is in the wrong position for 40 and 160. For both of those bands max dip is at the very low end of 3.5 dial marking. On 20, 15, and 10 the dip is in the correct position. On 10 I am only able to get 80 ma of plate current at min dip with CAR at max. This does indicate the 12BY7 is bad. I think I have a spare one somewhere around here - just have to look. When I switch to USB or LSB I am able to get the same levels of ALC deflection as FSK when I inject the 1 KHz. However, in CW mode I do not get any ALC meter deflection.

4) I will perform this step once the rig is working.

5) I am using the dummy load because I have a 40 meter dipole 8 feet off the ground (HOA) as my only antenna and not sure of the impedance it reflects. I have a Heath HM-15 SWR bridge but it doesn't have a watts reading. I just received an order from Mouser yesterday with the parts to build the dummy load that is on the K4EAA website. I am including the power measurement components so I will be able to know what my power out is. Once I am back on the air I will obtain an inline watt meter.

6) I haven't been on the air in 17 years and am wanting to get back on since I will be retiring in Jan and moving to somewhere that doesn't have a HOA. I have a HW-100 and a FT-101E that have sat in the garage for the last 17 years. I built the HW-100 back in 1968 and last used it in 1986. The FT-101 was working and I was using it on a daily basis when I went QRT at the end 1996. I bought this TS-820 10 years ago but have never used it. It has sat in the closet in my office since I bought it. I figured I would try to get it working first as it hasn't been exposed to extreme temperatures. I would be scared to power the other two up without replacing all the power supply caps first. My garage never drops below 100 four months out of the year.

Ray
AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

1. In LSB/USB should be 60ma resting plate current when you flip to send or key the mic. No indication on RF meter position until you modulate the rig (speak in mic). Can you see and adjust the resting plate current in SSB mode?

2. In Tune/CW will be plate current when you have RF drive (Car Pot advanced) only if you have RF drive as indicated by peaking the ALC indication with the Drive control.

Are you certain that Aux and TR relays are keying when you flip to send or key the mic? Sounds like they are based on seeing tube voltage dropping. Bias voltage at Finals control grid better not be dropping only 10%. It should change from approx -100vdc cutoff bias to approx -55vdc operating bias. If not then plate current and no RF output.

3. You can try a new 12BY7A as easy to do, but your rig has the diagnostic meter you need. Turn off SG switch and place rig in CW mode and peak the ALC indication by advancing the Car pot. Should be able to get full scale meter deflection (FSD) and hold there a few seconds on each band without the ALC indication falling off. Should get FSD with Car Pot advanced no more than approx 1000 to 1100. Rest between each band test as Driver tube is running class A (full plate current).

4 If RF detector is pegging at 70ma plate current then turn down the sensitivity pot. You always have to adjust the sensitivity pot. Set it for approx 2/3 deflection at 100 watts out. Would have been handy if KW would have put the pot on the front panel. They provided this meter position as it is better to load a Class AB1 linear amp by tuning for max rf output without exceeding plate dissipation than using the old dip and load method. They also provided it as external wattmeters were not common and they wanted the radio to be instrumented to be stand alone.

5. I would not use a 50 watt dummy load. If you must then have to realize all dummy loads have a duty cycle. Can use it but have to limit key down time.

6. When you get a couple of bucks ahead suggest you get an external wattmeter. Makes a good Loading aid and a good diagnostic tool. Drake W4, Heath HM-102, any of the MFJs are good and give you a SWR bridge and Wattmeter in one piece of test gear. Having actual output wattage tells you a lot more than looking at relative RF output power by measuring rf voltage at SO-239 or measuring the temperature of your dummy load.

I have a Kenwood TS-820S. Receive is working fine. Strange transmit problem.

When the Mode switch is the Tune, CW, USB, or LSB postion and I operate the Send switch I get no plate current and no output. When the switch is in the FSK position, I get almost normal plate current and can tune the rig to about 3/4 full power out. I can only get the load and plate controls to 160 ma into my dummy load with carrier control at max. Maybe a bad 12BY7 preventing full power out.

The other strange thing is when the meter switch is in the RF position, I can only increase the carrier control to about 70 ma plate current before the meter pegs when in FSK mode.

My 50 watt dummy load doesn't have a power indicator but I know the transmitter is putting out decent power in FSK mode as the resistors in the dummy load are getting warm.

Voltages (SG, Plate, Bias) are all normal. They drop about 10% when switching from receive to transmit mode. This drop happens in all postions of the mode switch, not just the FSK mode.

This makes no sense as in most cases the Tune and CW contacts of S6 are tied together. And S6-2 ties Tune, CW, and FSK together. Has anyone seen this issue before or give me an idea where to look for the problem?

Ray,
AB7HE

Dave,

I have VFO set to 14.175. With Car pot at 1200, in CW mode I get 40mV P-P in RX mode. When I flip the Send switch, the signal stays at 40 mV but it is no longer a sine wave. It is some kind of more or less sine wave with a lot of noise on it. With the Car pot at max, the noisy sinewave increases to 60 mV P-P in Send mode.

In FSK mode with Car at 1200 I get 250mV P-P in Send mode. With Car at Max I get 800 mV P-P in Send mode.

At Conn RF1-10 I get 140mV P-P in CW Send mode. I get 800mV P-P in FSK Send mode.

At the mixer output (Q1 and Q8 side of C8) I get 100 mV P-P in CW Send mode. I get 1V P-P in FSK Send mode. The signal at that point is not a sinewave but seems to have multiple signals. Probably some LO feedthrough on the mixer. The frequency counter agrees with the Kendwood readout as 14.1748 MHz.

Ray:

Sorry about Q10 vs Q18. My fingers work better than what is left of my brain.

The 3 conductor plug should be positioned in forward position toward the front panel.

One thing we did not talk about is whereiyou should have the Car Level Pot set to take these measurements.

The TX Level Diagram is shown in the Service Manual. These levels were taken by Kenwood by loading the rig to approx 100 watts out at 14.175mhz and then turn the SG switch off and leave Car pot alone and Drive control alone.

Since you have no RF output in CW mode I suggest you do this for remainder of the readings:

1. VFO 14.175
2. Peak the Drive Control on receiver noise or the marker signal
3. Car Level Pot 1200
4. Heater on
5. SG switch off
6. Flip to Send to take RF drive levels

So the differences in voltages may be due to where we each have our Car Level pot set at.

Suggest you measure the voltage and frequency of the TIF signal at IF-3 Pin 2 one more time and it should be approx 250mv rms or 700mv P-P @ 8830.7mhz.

If you have close to this time to move on to the RF board. I must say this is getting a little odd as you have good output ini SSB and FSK which tells us you have good TIF level and the TX Mixer on RF Board is working which means you have good VCO (LO to the mixer).

Are you 100% certain you have no CW RF output on all bands? If so, then proceed on to the RF board with Heaters On and SG off and rig peaked as noted above.

You should have close to the values noted on the TX Level Diagram. At Conn RF-1 Pin 10 the 8.830 TIF signal level is approx 38mv rms or 108 P-P.

At output of TX Mixer should have approx 1.5v rms or 4.2v P-P rf drive at MD. At MD frequency will now be 14.175mhz transmit frequency.

If you have no RF drive or very weak at MD then need to measure the VCO level and frequency at RF-1 pin 4 and on board at TP-1. Should be close to 1.0v rms level. If no VCO try on other bands.

We are making good progress. Your Tek 2445 is perfect scope for KW Hybrid work and you apparently know how to use it and can read a schematic and can locate points on these high density boards to take measurements. This really helps.

Based on your report of no RF output in CW mode I would have thought we would have found no TIF sig at output of the IF board. TIF is not band specific and often is caused by no output from the Bal Modulator, This is why I had you start by testing for bias voltage and LO signal available. Never expected that we would be at the RF board and TX Mixer based on good RF output on other modes.

Terry,

I read a little over 700mV at the drain of Q18 (actually the backside of C92 feeding the coax). I think you meant Q18 instead of Q10.

D7 and D8 are the CW switching diodes. With the mode switch in CW position, I have 2.98 volts on the anode of D7 and 2.34 volts on the cathode. I have 10.0 volts on the anode of D8 and 9.40 volts on the cathode. These voltages are there in both RX and TX, just a few 10ths of a volt lower in TX mode.

Can you confirm how the 3 pin cable ofr IF2 is supposed to plug in? It only has 3 wires but there are 5 pins on the IF board at that point. According to the chassis wiring diagram, only the first 3 pins are used as they come from S6-1.

I don't think there is anything wrong with the CW filter and the switching diodes as the CW filter works fine in RX mode.

I have 400mV P-P on Gate 1 of Q1 instead of the 160mV when flipping Send. I also have 2400mV P-P on the drain instead of 1000mV when flipping Send.

TIF signal on Conn IF-3 is 400mV P-P and the sine wave isn't quiet as clean there as it is on the drain of Q1.

Hopefully we are making progress.

Ray AB7HE

Ray:

Good job. Much better.

If I understand your chart you are telling me that you have approx 640mv P-P @ 8.83077 at TP-5 in CW mode with rig flipped to Send (heaters off and SG switch off). 900mv P-P is attainable by adjusting T1 on CAR-2 board, but can do later unless you want to peak it now. 640mv will work for testing.

If this is true then you have confirmed that you have the two things you need at the Balanced Mod to produce RF output from it in CW mode. 1. Offset bias voltage and 2. Proper Carrier freq and level.

From the BM output the CW signal is routed to the Crystal IF Filter and then to Q1 the Transmit IF Amp or TIF amp. TIF signal leaves the IF board and is routed to the RF board to the TX Mixer where it is mixed with VCO to produce the actual transmit rf drive signal. No TIF signal and there will be no RF drive and no RF output. Also no VCO or low VCO level and no rf drive. Lets validate that we have TIF signal in CW mode first.

Unfortunately KW didnt provide a nice test point at the output of the Balanced Mod to measure the DSBSC signal in SSB mode or the Carrier in CW mode. However, you can get on the Drain of Q10 with a hat pin or floral arrangement pin and mini-grabber test lead. If you locate the BM ring diodes D26-D29 and then output Xfmr T10 you will see Q10. It is a metal can dual gate mosfet. Looking down on the can the Drain is the upper right lead. You should read approx 800mv P-P here. This signal is routed to the Xtal filter thru switcing diodes.

Do you have the CW filter installed. It is rare but could have a bad filter. More common to have a bad switching diode.

After signal passes thru the Xtal filter it is applied to Gate 1 of TIF amp Q1. It is also a metal can dual gate mosfet and sits outside and almost between the two filters at the inboard end. Looking down on Q1 Gate 1 is at 1200. Should have approx 160mv P-P here. The Drain is at 0600 and should have approx 1000mv P-P. TIF output is on Conn IF-3 Pin 2 and should have approx 850mv P-P here. You can jump right to measuring TIF output if you want and if good then off to the RF board.

We know that you have TIF output in FSK mode as you reported good RF output in that mode. I dont kow if you keyed rig in FSK and noted the 170hz shift or not, but not important right now. Also, you should have noted that the RF output in FSK is lower as the 820 lowers the Finals Screen Grid voltage in FSK mode so the tubes plate dissipation is not exceeded in this high duty cycle mode.

That should be enough for now.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

This is what I am seeing:
TP-5 and CJ3-CA2 have the same levels in CW and FSK modes: 820mV P-P in RX mode. Flipping Send switch the level drops to 640mV P-P. I have a Tektronix 2445 Scope and have the probe in 10X to prevent loading the circuit.

Frequencies measured at CJ3-CA2:
RX mode FSK - 8.828414 - TX mode FSK 8.830620
RX mode LSB - 8.828414 - TX mode LSB 8.828579
RX mode USB - 8.831460 - TX mode USB 8.831625
RX mode CW - 8.831460 - TX mode CW 8.830777

Frequencies measured at TP-5:
RX mode FSK - 8.828410 - TX mode FSK 8.830616
RX mode LSB - 8.828410 - TX mode LSB 8.828575
RX mode USB - 8.831450 - TX mode USB 8.831622
RX mode CW - 8.831446 - TX mode CW 8.830773

I am using a Simpson 710 Frequency counter. Specs say 1 Meg input shunted by 30 pF. The slight differences in frequency readings between CJ3-CA2 and TP-5 is probably due to the cable capacitance of the cable between IF5-13 and CJ3-CA2.

I have been taking all of these measurements with the SG switch turned off and the heater switch turned off.

Ray:

I mis-spoke in Item 2 when I said you cant measure carrier at TP-5 in Rx in any of the mode switch positions. There will be legitimate carrier but not of interest.

There will be Carrier at CA-2 and TP-5 in Rx in all positions of the mode switch that you should see, but it is meaningless for CW Tx operation. It was not correct for me to label it as "Leakage" signals.

It is there by design but not for Rx or Tx operation. CA-1 Carrier Osc signals are coupled to the CAR-2 board to amp Q3 and then on to TP-5 at IF board and then sampled and sent to the CCR lead to provide carrier oscillator signals for the Counter Mixer Board. So the carrier osc signals you were measuring at each position of the mode switch in Rx are there by design to feed the counter, but of no interest to us as not utilized for the BM and CW transmit.

So you will see approx 250mv rms at 8831.50 mhz in CW and LSB and 250mv at 8828.5mhz in LSB and FSK, but not used by the BM. BM is not used in Rx operation. So disregard these signal other than the low levels you measured cannot be correct if your counter is working properly. I suspect you are not using O-scope properly. Are you using a 10X probe?

What I meant to say is at CA-2 and TP-5 the only frequency and level we care about is in CW and FSK positions of the mode switch in Tx. CA-2 carrier oscillator should be approx 250mv rms @ 8830.70mhz when in CW and FSK mode when flipped to send. This is what you are trying to validate. Measure at TP-5 in FSK as you know it is working. So use it to get your O-scope set up correctly and you can see approx 850mv P-P at 8830.7mhz. Once you can read that on your O-scope now switch to CW mode and flip to send to measure carrier osc signal level at TP-5.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Yes this new format gives me problems as well.

1. You are getting proper dc bias voltage to the BM. You need to confirm you are getting the Carrier Osc signal.

2. You cannot measure any Carrier freq or level at TP-5 in RX for any position of the mode switch. You may read some leakage signals in RX mode but meaningless. The BM is only used for TX and not RX. Only time you can measure any meaningful Carrier Osc frequency or level at TP-5 is in TX with the mode switch in CW or FSK. Carrier in RX mode is applied to another Mixer called the Product Detector and it arrives at IF board on IF-4 C1A terminal. You have separate Carrier Oscillators for RX and TX.

Also, the Car Level Pot has nothing to do with the Carrier Osc levels produced on the CAR Assembly Unit. The Car level pot unbalances the balanced modulator and determines the carrier output level from the BM.

You really need to measure CA-2 produced on the CAR-2 board. If you do not have 300mv of 8830.7mhz at TP-5 in CW mode when you flip to Send then you have to work your way back from TP-5 to CAR-2 board. CA2 can be checked on the 7th terminal up on the white terminal block on the CAR-2 board. On the IF board it comes in on Conn IF-5 pin 13.

At this point you have not confirmed that you have CAR-2 Q1 Oscillator running and available.

3. The DC voltages that you measured at D1 prove that you are getting the turn on voltages for Buffer amp Q2 so if Q1 is oscillating should get CW TX Carrier at CJ-3 and on to the IF board if all connectors are good.

You may have to adjust the frequency and output level but can talk about that later.

Suggest you buy a Freq Counter. Can measure Freq roughly with O-scope. Some measure and display Freq (may or may not do so accurately) and some require using F=1/T and not accurate enough for adjusting the Oscillators in the KW hybrids.

Terry K9TW

Let's try this again. For some reason yahoo has been mangling my posts. This has been a problem ever since they went to this new stupid format they are using.

Measuring at TP-2 the voltage varies from 16 mV to .443V when adjusting the CAR control in both FSK and CW mode. On Conn IF-5 at the CV terminal, the voltage varies from .12V to 8.95V in both FSK and CW mode when adjusting the CAR control.

Also, on the FIX VOX board FIX3-11 is grounded with no key plugged in. Plugging a key in, FIX3-11 follows the key (open key up, grounded key down).

I have cleaned the contacts on the Mode switch and checked for broken wires.

At TP-5 I measure 8.831434 MHz at .64V P-P (on scope) in all positions of the mode switch without the Send switch flipped. When I flip the Send switch the voltage drops to .48V P-P. The CAR control has no affect on the signal level with the Send switch in either position.

I measure 8.97V at the CW terminal on CAR-2 when I flip the Send switch. I measure 8.94V at the anode of D1 and 8.19V at the cathode when the Send switch is flipped.

I have a couple of multimeters, a 150 MHz analog scope, 100 MHz digital scope, W7ZOI power meter, and a KA7EXM power meter. I feel comfortable taking measurements anywhere inside the radio including the Final Cage.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

For some reason I cannot read your entire response? It appears you are reporting back that you have good bias voltage available at the BM from the Car Pot. In CW TX mode you need this bias voltage and you need the local oscillator (LO) or Carrier to produce an output. Which in this case it is 8.830.70mhz CA-2 produced on the CAR-2 Unit.

You are getting CA-2 Carrier in FSK mode so it tells me the Crystal and the soldering at its pins have to be good.

If you have a RF millivolt meter or O-scope you can measure the 8830.7 mhz Carrier at the IF board at TP-5.TP-5 is tucked back in the corner under the chassis side rail. With rig in CW mode flip to send and measure the level and the frequency at TP-5. It should be approx 300mv rms or approx 850mv P-P on a scope at 8830.70mhz.

I would measure the level first before you look at it with a Freq Counter as the counter may pull the level down. If you dont have a means to measure CA-2 Carrier level and frequency then at minimum measure CW terminal at CAR-2 Unit board to make sure you are getting CW TX bias voltage.

If you remove the 2 screws that secure the cover you will see a white 10 pin connector. The 3rd pin from the Crystal is the CW terminal. When you flip to send in CW mode should see approx 9.0vdc here. If you have 9vdc and still no output then suspect bad switching diode D1. D1 is close to the Crystal and you can measure the voltage at its anode and cathode. When you flip to send in CW mode should read approx 9vdc on the anode and approx 8.3vdc on the cathode. Note: The 9vdc will depend on where the AVR regulated 9vdc has been set too.

Ray

I forgot to mention where I am going with this (if not obvious) is a bad/dirty Mode switch contact or a broken wire at the mode switch in CW mode. The fact that you have output in FSK tells me that you do have approx 0.0 to 0.60vdc at TP-2 which then means the path from CV to the BM is good.

If you have no DMM, VOM, or VTVM the mode switch in a TS820 is an open deck type and pretty accessible with bottom cover off so you should be able to apply some deoxit and canned air to clean the contacts.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK well that would have been a quick fix and not first time so had to ask.

What test gear do you have and what is your comfort level to take measurements inside the rig?

When you inject audio into mic line and get output it tells you that your Balanced Modulator is working. In CW mode to produce output from the BM the Car Pot provides variable DC voltage to bias on the ring diodes. It is derives this bias voltage from regulated 9vdc from AVR board thru mode switch contacts.

The BM is on the IF board. Need to measure at Conn IF-5 at the CV terminal. Should see variable 0 to 9vdc at CV as you adjust the Car Pot thru its range.

Then measure at TP-2 and should see approx 0.0 to 0.70vdc as you adjust the Car Pot.

Ray:

Do you have a key in the key jack? If so remove it or key the key with Car Pot advanced. Cant load rig in CW mode if you have a key in key jack and it isnt closed. Brings back memories of the J-38 slider bar.

We can talk about plate dip not occurring at right place when we get CW working.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

Thanks for the comments.

1) I have 60 ma of current when I flip Send switch in CW, USB, and LSB modes. I don't have a microphone as I only operated CW back when I was on the air. I have a 1KHz tone generator and connected it to the microphone input. When I do this and increase MIC control in both USB and LSB I am able to drive plate current to the same 160 ma (on 20 meters) that I get in the FSK mode. So it appears CW is the only mode that isn't functioning.

2) I tuned the rig to the max power out (IP 160 ma) into the dummy load in the FSK position. I then switch to CW mode but the IP stays at 60 ma. This is with the CAR control at max (10 mark). Bias voltage drops from -100 to -63 volts when I flip Send switch in CW mode.

3) In the FSK mode I get almost FSD with CAR control at max on 20 meters in the ALC position. I am only 2 tick marks away from FSD. On 80, 40, and 160 I am able to get FSD at lower levels of the CAR control. However, when I turn SG back on and tune, the plate dip is in the wrong position for 40 and 160. For both of those bands max dip is at the very low end of 3.5 dial marking. On 20, 15, and 10 the dip is in the correct position. On 10 I am only able to get 80 ma of plate current at min dip with CAR at max. This does indicate the 12BY7 is bad. I think I have a spare one somewhere around here - just have to look. When I switch to USB or LSB I am able to get the same levels of ALC deflection as FSK when I inject the 1 KHz. However, in CW mode I do not get any ALC meter deflection.

4) I will perform this step once the rig is working.

5) I am using the dummy load because I have a 40 meter dipole 8 feet off the ground (HOA) as my only antenna and not sure of the impedance it reflects. I have a Heath HM-15 SWR bridge but it doesn't have a watts reading. I just received an order from Mouser yesterday with the parts to build the dummy load that is on the K4EAA website. I am including the power measurement components so I will be able to know what my power out is. Once I am back on the air I will obtain an inline watt meter.

6) I haven't been on the air in 17 years and am wanting to get back on since I will be retiring in Jan and moving to somewhere that doesn't have a HOA. I have a HW-100 and a FT-101E that have sat in the garage for the last 17 years. I built the HW-100 back in 1968 and last used it in 1986. The FT-101 was working and I was using it on a daily basis when I went QRT at the end 1996. I bought this TS-820 10 years ago but have never used it. It has sat in the closet in my office since I bought it. I figured I would try to get it working first as it hasn't been exposed to extreme temperatures. I would be scared to power the other two up without replacing all the power supply caps first. My garage never drops below 100 four months out of the year.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

1. In LSB/USB should be 60ma resting plate current when you flip to send or key the mic. No indication on RF meter position until you modulate the rig (speak in mic). Can you see and adjust the resting plate current in SSB mode?

2. In Tune/CW will be plate current when you have RF drive (Car Pot advanced) only if you have RF drive as indicated by peaking the ALC indication with the Drive control.

Are you certain that Aux and TR relays are keying when you flip to send or key the mic? Sounds like they are based on seeing tube voltage dropping. Bias voltage at Finals control

grid better not be dropping only 10%. It should change from approx -100vdc cutoff bias to approx -55vdc operating bias. If not then plate current and no RF output.

3. You can try a new 12BY7A as easy to do, but your rig has the diagnostic meter you need. Turn off SG switch and place rig in CW mode and peak the ALC indication by advancing the Car pot. Should be able to get full scale meter deflection (FSD) and hold there a few seconds on each band without the ALC indication falling off. Should get FSD with Car Pot advanced no more than approx 1000 to 1100. Rest between each band test as Driver tube is running class A (full plate current).

4 If RF detector is pegging at 70ma plate current then turn down the sensitivity pot. You always have to adjust the sensitivity pot. Set it for approx 2/3 deflection at 100 watts out. Would have been handy if KW would have put the pot on the front panel. They provided this meter position as it is better to load a Class AB1 linear amp by tuning for max rf output without exceeding plate dissipation than using the old dip and load method. They also provided it as external wattmeters were not common and they wanted the radio to be instrumented to be stand alone.

5. I would not use a 50 watt dummy load. If you must then have to realize all dummy loads have a duty cycle. Can use it but have to limit key down time.

6. When you get a couple of bucks ahead suggest you get an external wattmeter. Makes a good Loading aid and a good diagnostic tool. Drake W4, Heath HM-102, any of the MFJs are good and give you a SWR bridge and Wattmeter in one piece of test gear. Having actual output wattage tells you a lot more than looking at relative RF output power by measuring rf voltage at SO-239 or measuring the temperature of your dummy load.

I have a Kenwood TS-820S. Receive is working fine. Strange transmit problem.

When the Mode switch is the Tune, CW, USB, or LSB postion and I operate the Send switch I get no plate current and no output. When the switch is in the FSK position, I get almost normal plate current and can tune the rig to about 3/4 full power out. I can only get the load and plate controls to 160 ma into my dummy load with carrier control at max. Maybe a bad 12BY7 preventing full power out.

The other strange thing is when the meter switch is in the RF position, I can only increase the carrier control to about 70 ma plate current before the meter pegs when in FSK mode.

My 50 watt dummy load doesn't have a power indicator but I know the transmitter is putting out decent power in FSK mode as the resistors in the dummy load are getting warm.

Voltages (SG, Plate, Bias) are all normal. They drop about 10% when switching from receive to transmit mode. This drop happens in all postions of the mode switch, not just the FSK mode.

This makes no sense as in most cases the Tune and CW contacts of S6 are tied together. And S6-2 ties Tune, CW, and FSK together. Has anyone seen this issue before or give me an idea where to look for the problem?

Ray,
AB7HE

Some more information to the group. I checked filament voltage at pin 2 on V1, the 6146B. It's at 12 VAC without the tubes inserted, as it should be. However, with the tubes in, the voltage is at 140ma VAC. I would imagine it should stay at 12 VAC. I checked the HV, and the tubes are at 930 V when power is on. The driver tube filaments are also not on when the HT switch is ON.

I checked the cathode resistors and they show 5 OHMS to ground.

I'm wondering why the filament voltage is dropping like that, is this normal?

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Hello, recently acquired a TS-820. The receive works great.

However, when attempting the Tuning procedure (Checking that all controls are set according to the manual), the ALC meter did not move at the first step. I checked the Idling current and it stays at zero. Removing the cover, I checked to see if the filaments on the 6164B's light up with the H. Switch on. They do not light up.

With HV set on the meter, I do read a little over 9 on the scale.

Where are some common places that would exhibit these symptoms in the transmitter portion of the radio so that I have a starting point on what to check. Do I check if the SG switch is functional, H. Switch? External VFO cable is good. I checked that and all pins have continuity.

Any other starting bases begin troubleshooting?

Thank you!

Please to clarify??

"140 milliAmperes Volts Alternating Current" ?????

One or the other. (milli-)Amperes, or Volts. Which?

Do you mean the tube CURRENT is 140 mA? Or that the tube VOLTAGE drops from 12 Volts AC no-load, to 140 thousandths of one VOLT??

Are you measuring from Pin 2 to chassis ground?

To measure the current, you would need to have LIFTED or broken the wire onto Pin 2 and insered the Ammeter into the circuit, one lead to the lifted wire, the other to the Pin 2 terminal.

For voltage, from Pin 2 with one lead, ground with the other lead, to measure the voltage drop when the heater is turned on.

What sort of meter are you using, by the way? An old-fashioned VTVM? Or a modern DMM? (Won't make a lot of difference, either way, for measuring heater voltage, just curious.) Or are you actually measuring current, using an Ameter or milliAmmeter?

How can the voltage be 140ma VAC? Your issue is a simple one. No need to check high voltage or alignment of the radio. I believe the voltage to a 646 should be 6.3 volts, not 2 volts for one thing and I also believe that the two tubes may be in series. Try checking the RESISTANCE of the filaments of each tube. Do you have a schematic? You may want to trace right back to the transformer. You may have something as simple as a bad switch, quite common for those to go bad. Brad KB2CHY

Some more information to the group. I checked filament voltage at pin 2 on V1, the 6146B. It's at 12 VAC without the tubes inserted, as it should be. However, with the tubes in, the voltage is at 140ma VAC. I would imagine it should stay at 12 VAC. I checked the HV, and the tubes are at 930 V when power is on. The driver tube filaments are also not on when the HT switch is ON.

I checked the cathode resistors and they show 5 OHMS to ground.

I'm wondering why the filament voltage is dropping like that, is this normal?

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Hello, recently acquired a TS-820. The receive works great.

However, when attempting the Tuning procedure (Checking that all controls are set according to the manual), the ALC meter did not move at the first step. I checked the Idling current and it stays at zero. Removing the cover, I checked to see if the filaments on the 6164B's light up with the H. Switch on. They do not light up.

With HV set on the meter, I do read a little over 9 on the scale.

Where are some common places that would exhibit these symptoms in the transmitter portion of the radio so that I have a starting point on what to check. Do I check if the SG switch is functional, H. Switch? Ex ternal VFO

cable is good. I checked that and all pins have continuity.

Any other starting bases begin troubleshooting?

Thank you!

Leave the driver and both final tubes in their sockets. Make sure the
SEND switch is DOWN BEFORE you power up the 820! Power up the 820 and
set the HEATER switch to ON . Use caution when measuring filament
voltage since there are high voltages present on the final unit board!!!

Measure the final tube filament voltage at the tube sockets starting
with final tube V1 pin 2.

Set your volt meter to measure AC (25VAC)
Connect the "BLACK" meter lead to the 820's chassis
Connect the "RED" meter lead to final tube V1's pin 2.

The meter should show 12VAC. If it does then move ONLY the RED meter
lead to final tube V1's pin 7, the meter should show 6VAC. If that's
what you see but both final tube filaments are not lit then final tube
V2 filament is most likely OPEN.

Measure the filament voltage of the driver tube, V1, on the RF unit board

Connect the "RED" meter lead to driver tube socket pin 5
Connect the "BLACK" meter lead to the 820's chassis.

The meter should show 12VAC. If it does BUT the driver tube filament is
NOT lit then the driver tube's filament is most likely OPEN.

I have no idea what "140ma VAC" means, that makes no sense!

Cycling the band switch and checking the final tube cathode resistors
has nothing to do with the driver and both final tube filament problems.

NO the switch is NOT bad! Did you read the entire thread? It has already been determined that 12VAC IS present at pin 2 of final tube V1 (see below) so the switch can't be bad so why suggest it is!!!

"/*I checked filament voltage at pin 2 of V1, the 6146B. It's at 12VAC without the tubes inserted, as it should be*//*.*/"

You believe the 820 filament voltage to the 6146 filaments should be 6VAC? Why would you say that when the final tube filaments are wired in "series"? That would put "3VAC" across each final tube filament!! If you look at the 820 schematic you will clearly see that the final tube filaments are, in fact, wired in "series" AND the driver and both final tube filament voltage IS "12VAC" not "6VAC" as you thought!

The original questioner said “the 820 filament voltage to the 6146 filaments should be 6VAC”. I suspect that what he meant was ”the 820 filament voltage across each of the 6146 filaments should be 6Vac” which would be correct. I think it’s a case of using an ambiguous form of words rather than a misapprehension that 6146 valves have a 3V filament.

Like everyone else, I am at loss to see where 140ma VAC comes from, even if 140ma, 140 mVAC or 140VAC was meant.

Mike, I said the switch could be bad because of the 140ma VAC reading. Obviously someone read something wrong. The filaments of the 6146's are in series with 12 volts which that means 6VAC at each filament. !2 volts AC would go to the 12BY7. So the12BY7 is in PARALLEL with 2 6146's in series and voltage across each supplied to the tubes. No, I did not read the whole thread. It seems that some don't want to get all the spaces and such on their portable devices, so some stuff is cutoff. I usually look at the last response. After I saw the 140ma VAC reading I was not sure what kind of know how you had, so I attempted the simple and easy route. I know what the schematic says without looking at it and I NEVER said the voltage to the tubes was 6 VAC. I said it was 12VAC so there should be 6 VAC across EACH tube in the final cage. The 12BY7 would be 12 volts. You asked for help in this, and I responded in good faith. No reason to be so quick to bite off my head. The switch could be intermittent or where the contacts can't handle the current. If you say the switch is not bad, OK, just say so. I am only trying to help you get you through a simple series parallel circuit.

Oh by the way, 2 6146's in SERIES with 12 volts applied would put 6 volts at each filament. That is a true statement. The driver is fed across the transformer with 12 volts. I will let you read what you wrote and analyze that again. I never said the TOTAL voltage across two 6146's is 6VAC, you did. I said ONE tube is 6VAC so the tubes may be in series which would equal the 12 VAC applied. Brad KB2CHY

. I believe the voltage to a 6146 should be 6.3 volts, not 12 volts. Please READ what I wrote. You will see I said to "A" 6146, not both.

This is BASIC electricity/electronics knowledge that ALL hams should know how to do. However, unfortunately many members don't believe they need to know this stuff so we end up with how this thread has gone!

Tackling one problem at a time is what should be done. Once the filament issue is solved I suspect the loss of 60ma idling current will no longer exist.

Subject: Re: [TS-520_820_530_830] RE: Transmitter not working - No idling current, tubes not turning on.

The original questioner said â□□the 820 filament voltage to the 6146 filaments should be 6VACâ□□. I suspect that what he meant was â□□the 820 filament voltage across each of the 6146 filaments should be 6Vacâ□□ which would be correct. I think itâ□□s a case of using an ambiguous form of words rather than a misapprehension that 6146 valves have a 3V filament.

Like everyone else, I am at loss to see where 140ma VAC comes from, even if 140ma, 140 mVAC or 140VAC was meant.

Subject: [TS-520_820_530_830] RE: Transmitter not working - No idling current, tubes not turning on.

Some more information to the group. I checked filament voltage at pin 2 on V1, the 6146B. It's at 12 VAC without the tubes inserted, as it should be. However, with the tubes in, the voltage is at 140ma VAC. I would imagine it should stay at 12 VAC. I checked the HV, and the tubes are at 930 V when power is on. The driver tube filaments are also not on when the HT switch is ON.

I checked the cathode resistors and they show 5 OHMS to ground.

I'm wondering why the filament voltage is dropping like that, is this normal?

---In TS-520_820_530_830@yahoogroups.com, mailto:ts-520_820_530_830@yahoogroups.com wrote:

Hello, recently acquired a TS-820. The receive works great.

However, when attempting the Tuning procedure (Checking that all controls are set according to the manual), the ALC meter did not move at the first step. I checked the Idling current and it stays at zero. Removing the cover, I checked to see if the filaments on the 6164B's light up with the H. Switch on. They do not light up.

With HV set on the meter, I do read a little over 9 on the scale.

Where are some common places that would exhibit these symptoms in the transmitter portion of the radio so that I have a starting point on what to check. Do I check if the SG switch is functional, H. Switch? Ex ternal VFO cable is good. I checked that and all pins have continuity.

Any other starting bases begin troubleshooting?

Thank you!

Brad,

If you took my response as "biting you head off" then you took it wrong.

I am sorry Brad but I do not agree with the switch being intermittent. There is no evidence, at least at this stage, that indicates the switch is intermittent. The presence of 12VAC at pin 2 of V1 final tube indicates the switch is not bad or even intermittent. An intermittent switch could easily show the filaments lit then dying out without touching the switch but that has not been indicated.

Your wording of your response about the filament voltage to the final tube indicated to me that you thought the final tube filament voltage should be 6.3VAC not 12VAC. I am aware the filament voltage for the 6146 is 6.3VAC but the 6146 filaments, as I said, in the 820 are wired in series so the filament voltage in the 820 will be 12VAC. Your indication of the 6146 filament wiring was not clear, you hinted that the final tubes were in series, which they are.

I don't mean any disrespect to anyone but it gets very frustrating and annoying when trying to help someone and they don't listen. They ask for help yet when given a few simple easy steps to take, they don't follow or if they do they do other things they are not told to do which quite often confuses the issue! That happens a lot on this and other ham forums and groups and it gets very frustrating and annoying!

Also, members need to read an entire thread before responding. It's quite possible that your response could duplicate a response given a few hours or half a day earlier.

I am going to start back from the beginning. I just looked at the CAR-2 board schematic and the specs for oscillator frequencies. CW and FSK(space) use the same frequency (8830.7) so if FSK is working, CW should also be working. The default for FSK with nothing plugged into the FSK jack is space. Looking at the schematic, the CW carrier is keyed on at CJ2-CW through L1 and D1. FSK is keyed on at CJ2-FSK through L2 and D2. They both key the oscillator on at the same point. Since I am apparently not getting CW carrier in the Tune or CW postion, either L1 or D1 must be open. I will check these when I get home this evening.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Dave,

I have VFO set to 14.175. With Car pot at 1200, in CW mode I get 40mV P-P in RX mode. When I flip the Send switch, the signal stays at 40 mV but it is no longer a sine wave. It is some kind of more or less sine wave with a lot of noise on it. With the Car pot at max, the noisy sinewave increases to 60 mV P-P in Send mode.

In FSK mode with Car at 1200 I get 250mV P-P in Send mode. With Car at Max I get 800 mV P-P in Send mode.

At Conn RF1-10 I get 140mV P-P in CW Send mode. I get 800mV P-P in FSK Send mode.

At the mixer output (Q1 and Q8 side of C8) I get 100 mV P-P in CW Send mode. I get 1V P-P in FSK Send mode. The signal at that point is not a sinewave but seems to have multiple signals. Probably some LO feedthrough on the mixer. The frequency counter agrees with the Kendwood readout as 14.1748 MHz.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Sorry about Q10 vs Q18. My fingers work better than what is left of my brain.

The 3 conductor plug should be positioned in forward position toward the front panel.

One thing we did not talk about is whereiyou should have the Car Level Pot set to take these measurements.

The TX Level Diagram is shown in the Service Manual. These levels were taken by Kenwood by loading the rig to approx 100 watts out at 14.175mhz and then turn the SG switch off and leave Car pot alone and Drive control alone.

Since you have no RF output in CW mode I suggest you do this for remainder of the readings:

1. VFO 14.175
2. Peak the Drive Control on receiver noise or the marker signal

3. Car Level Pot 1200
4. Heater on
5. SG switch off
6. Flip to Send to take RF drive levels

So the differences in voltages may be due to where we each have our Car Level pot set at.

Suggest you measure the voltage and frequency of the TIF signal at IF-3 Pin 2 one more time and it should be approx 250mv rms or 700mv P-P @ 8830.7mhz.

If you have close to this time to move on to the RF board. I must say this is getting a little odd as you have good output ini SSB and FSK which tells us you have good TIF level and the TX Mixer on RF Board is working which means you have good VCO (LO to the mixer).

Are you 100% certain you have no CW RF output on all bands? If so, then proceed on to the RF board with Heaters On and SG off and rig peaked as noted above.

You should have close to the values noted on the TX Level Diagram. At Conn RF-1 Pin 10 the 8.830 TIF signal level is approx 38mv rms or 108 P-P.

At output of TX Mixer should have approx 1.5v rms or 4.2v P-P rf drive at MD. At MD frequency will now be 14.175mhz transmit frequency.

If you have no RF drive or very weak at MD then need to measure the VCO level and frequency at RF-1 pin 4 and on board at TP-1. Should be close to 1.0v rms level. If no VCO try on other bands.

We are making good progress. Your Tek 2445 is perfect scope for KW Hybrid work and you apparently know how to use it and can read a schematic and can locate points on these high density boards to take measurements. This really helps.

Based on your report of no RF output in CW mode I would have thought we would have found no TIF sig at output of the IF board. TIF is not band specific and often is caused by no output from the Bal Modulator, This is why I had you start by testing for bias voltage and LO signal available. Never expected that we would be at the RF board and TX Mixer based on good RF output on other modes.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I read a little over 700mV at the drain of Q18 (actually the backside of C92 feeding the coax). I think you meant Q18 instead of Q10.

D7 and D8 are the CW switching diodes. With the mode switch in CW position, I have 2.98 volts on the anode of D7 and 2.34 volts on the cathode. I have 10.0 volts on the anode of D8 and 9.40 volts on the cathode. These voltages are there in both RX and TX, just a few 10ths of a volt lower in TX mode.

Can you confirm how the 3 pin cable ofr IF2 is supposed to plug in? It only has 3 wires but there are 5 pins on the IF board at that point. According to the chassis wiring diagram, only the first 3 pins are used as they come from S6-1.

I don't think there is anything wrong with the CW filter and the switching diodes as the CW filter works fine in RX mode.

I have 400mV P-P on Gate 1 of Q1 instead of the 160mV when flipping Send. I also have 2400mV P-P on the drain instead of 1000mV when flipping Send.

TIF signal on Conn IF-3 is 400mV P-P and the sine wave isn't quiet as clean there as it is on the drain of Q1.

Hopefully we are making progress.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Good job. Much better.

If I understand your chart you are telling me that you have approx 640mv P-P @ 8.83077 at TP-5 in CW mode with rig flipped to Send (heaters off and SG switch off). 900mv P-P is attainable by adjusting T1 on CAR-2 board, but can do later unless you want to peak it now. 640mv will work for testing.

If this is true then you have confirmed that you have the two things you need at the Balanced Mod to produce RF output from it in CW mode. 1. Offset bias voltage and 2. Proper Carrier freq and level.

From the BM output the CW signal is routed to the Crystal IF Filter and then to Q1 the Transmit IF Amp or TIF amp. TIF signal leaves the IF board and is routed to the RF board to the TX Mixer where it is mixed with VCO to produce the actual transmit rf drive signal. No TIF signal and there will be no RF drive and no RF output. Also no VCO or low VCO level and no rf drive. Lets validate that we have TIF signal in CW mode first.

Unfortunately KW didnt provide a nice test point at the output of the Balanced Mod to measure the DSBSC signal in SSB mode or the Carrier in CW mode. However, you can get on the Drain of Q10 with a hat pin or floral arrangement pin and mini-grabber test lead. If you locate the BM ring diodes D26-D29 and then output Xfmr T10 you will see Q10. It is a metal can dual gate mosfet. Looking down on the can the Drain is the upper right lead. You should read approx 800mv P-P here. This signal is routed to the Xtal filter thru switcing diodes.

Do you have the CW filter installed. It is rare but could have a bad filter. More common to have a bad switching diode.

After signal passes thru the Xtal filter it is applied to Gate 1 of TIF amp Q1. It is also a metal can dual gate mosfet and sits outside and almost between the two filters at the inboard end. Looking down on Q1 Gate 1 is at 1200. Should have approx 160mv P-P here. The Drain is at 0600 and should have approx 1000mv P-P. TIF output is on Conn IF-3 Pin 2 and should have approx 850mv P-P here. You can jump right to measuring TIF output if you want and if good then off to the RF board.

We know that you have TIF output in FSK mode as you reported good RF output in that mode. I dont kow if you keyed rig in FSK and noted the 170hz shift or not, but not important right now. Also, you should have noted that the RF output in FSK is lower as the 820 lowers the Finals Screen Grid voltage in FSK mode so the tubes plate dissipation is not exceeded in

this high duty cycle mode.

That should be enough for now.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

This is what I am seeing:
TP-5 and CJ3-CA2 have the same levels in CW and FSK modes: 820mV P-P in RX mode. Flipping Send switch the level drops to 640mV P-P. I have a Tektronix 2445 Scope and have the probe in 10X to prevent loading the circuit.

Frequencies measured at CJ3-CA2:
RX mode FSK - 8.828414 - TX mode FSK 8.830620
RX mode LSB - 8.828414 - TX mode LSB 8.828579
RX mode USB - 8.831460 - TX mode USB 8.831625
RX mode CW - 8.831460 - TX mode CW 8.830777

Frequencies measured at TP-5:
RX mode FSK - 8.828410 - TX mode FSK 8.830616
RX mode LSB - 8.828410 - TX mode LSB 8.828575
RX mode USB - 8.831450 - TX mode USB 8.831622
RX mode CW - 8.831446 - TX mode CW 8.830773

I am using a Simpson 710 Frequency counter. Specs say 1 Meg input shunted by 30 pF. The slight differences in frequency readings between CJ3-CA2 and TP-5 is probably due to the cable capacitance of the cable between IF5-13 and CJ3-CA2.

I have been taking all of these measurements with the SG switch turned off and the heater switch turned off.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

I mis-spoke in Item 2 when I said you cant measure carrier at TP-5 in Rx in any of the mode switch positions. There will be legitimate carrier but not of interest.

There will be Carrier at CA-2 and TP-5 in Rx in all positions of the mode switch that you should see, but it is meaningless for CW Tx operation. It was not correct for me to label it as "Leakage" signals.

It is there by design but not for Rx or Tx operation. CA-1 Carrier Osc signals are coupled to the CAR-2 board to amp Q3 and then on to TP-5 at IF board and then sampled and sent to the CCR lead to provide carrier oscillator signals for the Counter Mixer Board. So the carrier osc signals you were measuring at each position of the mode switch in Rx are there by design to feed the counter, but of no interest to us as not utilized for the BM and CW transmit.

So you will see approx 250mv rms at 8831.50 mhz in CW and LSB and 250mv at 8828.5mhz in LSB and FSK, but not used by the BM. BM is not used in Rx operation. So disregard these signal other than the low levels you measured cannot be correct if your counter is working

properly. I suspect you are not using O-scope properly. Are you using a 10X probe?

What I meant to say is at CA-2 and TP-5 the only frequency and level we care about is in CW and FSK positions of the mode switch in Tx. CA-2 carrier oscillator should be approx 250mv rms @ 8830.70mhz when in CW and FSK mode when flipped to send. This is what you are trying to validate. Measure at TP-5 in FSK as you know it is working. So use it to get your O-scope set up correctly and you can see approx 850mv P-P at 8830.7mhz. Once you can read that on your O-scope now switch to CW mode and flip to send to measure carrier osc signal level at TP-5.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Yes this new format gives me problems as well.

1. You are getting proper dc bias voltage to the BM. You need to confirm you are getting the Carrier Osc signal.

2. You cannot measure any Carrier freq or level at TP-5 in RX for any position of the mode switch. You may read some leakage signals in RX mode but meaningless. The BM is only used for TX and not RX. Only time you can measure any meaningful Carrier Osc frequency or level at TP-5 is in TX with the mode switch in CW or FSK. Carrier in RX mode is applied to another Mixer called the Product Detector and it arrives at IF board on IF-4 C1A terminal. You have separate Carrier Oscillators for RX and TX.

Also, the Car Level Pot has nothing to do with the Carrier Osc levels produced on the CAR Assembly Unit. The Car level pot unbalances the balanced modulator and determines the carrier output level from the BM.

You really need to measure CA-2 produced on the CAR-2 board. If you do not have 300mv of 8830.7mhz at TP-5 in CW mode when you flip to Send then you have to work your way back from TP-5 to CAR-2 board. CA2 can be checked on the 7th terminal up on the white terminal block on the CAR-2 board. On the IF board it comes in on Conn IF-5 pin 13.

At this point you have not confirmed that you have CAR-2 Q1 Oscillator running and available.

3. The DC voltages that you measured at D1 prove that you are getting the turn on voltages for Buffer amp Q2 so if Q1 is oscillating should get CW TX Carrier at CJ-3 and on to the IF board if all connectors are good.

You may have to adjust the frequency and output level but can talk about that later.

Suggest you buy a Freq Counter. Can measure Freq roughly with O-scope. Some measure and display Freq (may or may not do so accurately) and some require using F=1/T and not accurate enough for adjusting the Oscillators in the KW hybrids.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Let's try this again. For some reason yahoo has been mangling my posts. This has been a problem ever since they went to this new stupid format they are using.

Measuring at TP-2 the voltage varies from 16 mV to .443V when adjusting the CAR control in both FSK and CW mode. On Conn IF-5 at the CV terminal, the voltage varies from .12V to 8.95V in both FSK and CW mode when adjusting the CAR control.

Also, on the FIX VOX board FIX3-11 is grounded with no key plugged in. Plugging a key in, FIX3-11 follows the key (open key up, grounded key down).

I have cleaned the contacts on the Mode switch and checked for broken wires.

At TP-5 I measure 8.831434 MHz at .64V P-P (on scope) in all positions of the mode switch without the Send switch flipped. When I flip the Send switch the voltage drops to .48V P-P. The CAR control has no affect on the signal level with the Send switch in either position.

I measure 8.97V at the CW terminal on CAR-2 when I flip the Send switch. I measure 8.94V at the anode of D1 and 8.19V at the cathode when the Send switch is flipped.

I have a couple of multimeters, a 150 MHz analog scope, 100 MHz digital scope, W7ZOI power meter, and a KA7EXM power meter. I feel comfortable taking measurements anywhere inside the radio including the Final Cage.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

For some reason I cannot read your entire response? It appears you are reporting back that you have good bias voltage available at the BM from the Car Pot. In CW TX mode you need this bias voltage and you need the local oscillator (LO) or Carrier to produce an output. Which in this case it is 8.830.70mhz CA-2 produced on the CAR-2 Unit.

You are getting CA-2 Carrier in FSK mode so it tells me the Crystal and the soldering at its pins have to be good.

If you have a RF millivolt meter or O-scope you can measure the 8830.7 mhz Carrier at the IF board at TP-5.TP-5 is tucked back in the corner under the chassis side rail. With rig in CW mode flip to send and measure the level and the frequency at TP-5. It should be approx 300mv rms or approx 850mv P-P on a scope at 8830.70mhz.

I would measure the level first before you look at it with a Freq Counter as the counter may pull the level down. If you dont have a means to measure CA-2 Carrier level and frequency then at minimum measure CW terminal at CAR-2 Unit board to make sure you are getting CW TX bias voltage.

If you remove the 2 screws that secure the cover you will see a white 10 pin connector. The 3rd pin from the Crystal is the CW terminal. When you flip to send in CW mode should see approx 9.0vdc here. If you have 9vdc and still no output then suspect bad switching diode D1. D1 is close to the Crystal and you can measure the voltage at its anode and cathode. When you flip to send in CW mode should read approx 9vdc on the anode and approx 8.3vdc on the cathode. Note: The 9vdc will depend on where the AVR regulated 9vdc has been set too.

On Conn IF-5 CV the voltage varies from .1 volts to 8.95 volts as I rotate the CAR control. On TP-2 the voltage varies from 16 mV to .443 volts as I rotate the CAR control. These

voltages are the same with the Mode switch in either CW or FSK mode.

Also, on the FIX VOX board, FIX3-11 is shorted to ground when the key is not plugged in. If I plug the key in, FIX3-11 follows the key, open with key up, ground with key down. I cleaned the mode switch and visually checked it for broken wires.

I have a couple of multimeters, a 150 MHz analog scope, a 100 MHz digital scope, a W7ZOI power meter, and a KA7EXM power meter. I feel comportable taking measurements anywhere inside the rig, including the final cage.

Ray

I forgot to mention where I am going with this (if not obvious) is a bad/dirty Mode switch contact or a broken wire at the mode switch in CW mode. The fact that you have output in FSK tells me that you do have approx 0.0 to 0.60vdc at TP-2 which then means the path from CV to the BM is good.

If you have no DMM, VOM, or VTVM the mode switch in a TS820 is an open deck type and pretty accessible with bottom cover off so you should be able to apply some deoxit and canned air to clean the contacts.

Terry K9TW

OK well that would have been a quick fix and not first time so had to ask.

What test gear do you have and what is your comfort level to take measurements inside the rig?

When you inject audio into mic line and get output it tells you that your Balanced Modulator is working. In CW mode to produce output from the BM the Car Pot provides variable DC voltage to bias on the ring diodes. It is derives this bias voltage from regulated 9vdc from AVR board thru mode switch contacts.

The BM is on the IF board. Need to measure at Conn IF-5 at the CV terminal. Should see variable 0 to 9vdc at CV as you adjust the Car Pot thru its range.

Then measure at TP-2 and should see approx 0.0 to 0.70vdc as you adjust the Car Pot.

Ray:

Do you have a key in the key jack? If so remove it or key the key with Car Pot advanced. Cant load rig in CW mode if you have a key in key jack and it isnt closed. Brings back memories of the J-38 slider bar.

We can talk about plate dip not occurring at right place when we get CW working.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

Thanks for the comments.

1) I have 60 ma of current when I flip Send switch in CW, USB, and LSB modes. I don't have a microphone as I only operated CW back when I was on the air. I have a 1KHz tone generator and connected it to the microphone input. When I do this and increase MIC control in both USB and LSB I am able to drive plate current to the same 160 ma (on 20 meters) that I get in the FSK mode. So it appears CW is the only mode that isn't functioning.

2) I tuned the rig to the max power out (IP 160 ma) into the dummy load in the FSK position. I then switch to CW mode but the IP stays at 60 ma. This is with the CAR control at max (10 mark). Bias voltage drops from -100 to -63 volts when I flip Send switch in CW mode.

3) In the FSK mode I get almost FSD with CAR control at max on 20 meters in the ALC position. I am only 2 tick marks away from FSD. On 80, 40, and 160 I am able to get FSD at lower levels of the CAR control. However, when I turn SG back on and tune, the plate dip is in the wrong position for 40 and 160. For both of those bands max dip is at the very low end of 3.5 dial marking. On 20, 15, and 10 the dip is in the correct position. On 10 I am only able to get 80 ma of plate current at min dip with CAR at max. This does indicate the 12BY7 is bad. I think I have a spare one somewhere around here - just have to look. When I switch to USB or LSB I am able to get the same levels of ALC deflection as FSK when I inject the 1 KHz. However, in CW mode I do not get any ALC meter deflection.

4) I will perform this step once the rig is working.

5) I am using the dummy load because I have a 40 meter dipole 8 feet off the ground (HOA) as my only antenna and not sure of the impedance it reflects. I have a Heath HM-15 SWR bridge but it doesn't have a watts reading. I just received an order from Mouser yesterday with the parts to build the dummy load that is on the K4EAA website. I am including the power measurement components so I will be able to know what my power out is. Once I am back on the air I will obtain an inline watt meter.

6) I haven't been on the air in 17 years and am wanting to get back on since I will be retiring in Jan and moving to somewhere that doesn't have a HOA. I have a HW-100 and a FT-101E that have sat in the garage for the last 17 years. I built the HW-100 back in 1968 and last used it in 1986. The FT-101 was working and I was using it on a daily basis when I went QRT at the end 1996. I bought this TS-820 10 years ago but have never used it. It has sat in the closet in my office since I bought it. I figured I would try to get it working first as it hasn't been exposed to extreme temperatures. I would be scared to power the other two up without replacing all the power supply caps first. My garage never drops below 100 four months out of the year.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

1. In LSB/USB should be 60ma resting plate current when you flip to send or key the mic. No indication on RF meter position until you modulate the rig (speak in mic). Can you see and adjust the resting plate current in SSB mode?

2. In Tune/CW will be plate current when you have RF drive (Car Pot advanced) only if you have RF drive as indicated by peaking the ALC indication with the Drive control.

Are you certain that Aux and TR relays are keying when you flip to send or key the mic? Sounds like they are based on seeing tube voltage dropping. Bias voltage at Finals control grid better not be dropping only 10%. It should change from approx -100vdc cutoff bias to approx -55vdc operating bias. If not then plate current and no RF output.

3. You can try a new 12BY7A as easy to do, but your rig has the diagnostic meter you need. Turn off SG switch and place rig in CW mode and peak the ALC indication by advancing the Car pot. Should be able to get full scale meter deflection (FSD) and hold there a few seconds on each band without the ALC indication falling off. Should get FSD with Car Pot advanced no more than approx 1000 to 1100. Rest between each band test as Driver tube is running class A (full plate current).

4 If RF detector is pegging at 70ma plate current then turn down the sensitivity pot. You always have to adjust the sensitivity pot. Set it for approx 2/3 deflection at 100 watts out. Would have been handy if KW would have put the pot on the front panel. They provided this meter position as it is better to load a Class AB1 linear amp by tuning for max rf output without exceeding plate dissipation than using the old dip and load method. They also provided it as external wattmeters were not common and they wanted the radio to be instrumented to be stand alone.

5. I would not use a 50 watt dummy load. If you must then have to realize all dummy loads have a duty cycle. Can use it but have to limit key down time.

6. When you get a couple of bucks ahead suggest you get an external wattmeter. Makes a good Loading aid and a good diagnostic tool. Drake W4, Heath HM-102, any of the MFJs are good and give you a SWR bridge and Wattmeter in one piece of test gear. Having actual output wattage tells you a lot more than looking at relative RF output power by measuring rf voltage at SO-239 or measuring the temperature of your dummy load.

I have a Kenwood TS-820S. Receive is working fine. Strange transmit problem.

When the Mode switch is the Tune, CW, USB, or LSB postion and I operate the Send switch I get no plate current and no output. When the switch is in the FSK position, I get almost normal plate current and can tune the rig to about 3/4 full power out. I can only get the load and plate controls to 160 ma into my dummy load with carrier control at max. Maybe a bad 12BY7 preventing full power out.

The other strange thing is when the meter switch is in the RF position, I can only increase the carrier control to about 70 ma plate current before the meter pegs when in FSK mode.

My 50 watt dummy load doesn't have a power indicator but I know the transmitter is putting out decent power in FSK mode as the resistors in the dummy load are getting warm.

Voltages (SG, Plate, Bias) are all normal. They drop about 10% when switching from receive to transmit mode. This drop happens in all postions of the mode switch, not just the FSK mode.

This makes no sense as in most cases the Tune and CW contacts of S6 are tied together. And S6-2 ties Tune, CW, and FSK together. Has anyone seen this issue before or give me an idea where to look for the problem?

Ray,
AB7HE

Tovarishch, the problem is the mixed terms you used here. Nobody is trying to snipe at you, we are just confused as all get-out as to what you could POSSIBLY mean.

You used, as it shows above, the term

140 MILLI-AMPERES VOLTS ALTERNATING CURRENT

when I expand all the abbreviations.

Milli-amperes are NOT Volts. You measure them in totally different ways, for one thing, with totally different meters. (Can be combined into one box, certainly, but an ammeter is placed in series with the circuit under test, and volts are measured with the meter in parallel to the part being checked.)

Is the correct unit MILLIVOLTS, perhaps??? Abbreviated "mV" ?? Because milli-Ampere Volts is TRULY confusing.

You should get 12 Volts AC from Pin 2 of V1 to chassis ground, and only 6 Volts AC at pin 7 of V1 (which is connected directly to pin 2 of V2, the other 6146 tube; it is just the other end of the same wire).

Heater switch ON of course. Flip it to OFF and that should drop to Zero volts. It might be worth a check, this will make certain you don't have a wonky heater switch; they do go out of order sometimes.

Really, it's not a personal attack. We just want to figure out what Milli-Amperes Volts really meant.

Are you talking Dave or Terry ? If someone is helping you off list I can back away as I have a pretty full plate right now.

I am not clear where you are measuring this 40mv P-P signal at?

Before I go I will mention that it is normal to not have a clean sine wave at TIF. It does have harmonic content and it is as you say due to LO mixing action. In this case it is coming from the VCO signal feeding back from the TX Mixer on RF board to the IF board.

This is easy to confirm with a TS-830 as you can easily unplug the VCO cable from the PLL board and the TIF signal will then be a nice clean 8.830mhz sine wave.

Dont worry about the complex waveform. Should still be able to get a reasonably close TIF measurement. It may not match exactly the levels on the TX Level Diagram,but you can compare it to the level you get with FSK carrier oscillator.

I dont use a O-scope to run TX Level diagrams once I get to the output of the TIF amp. I use a Boonton RF Millivolt meter and measure levels in rms and the "dirty" TIF signal presents no problem.

I have a new digital O-scope and it has a variety of digital filters. If I set it for a LP filter with a roll off frequency of 10mhz I can get a pretty clean 8.830 TIF sine wave display.

I dont know the Tek 2445 capability in this regard.

One final reminder is that good TIF signal level of approx 38mv rms or 107mv P-P is based on the premise that you accurately measured CA2 at the iF board of approx 300mv rms or 850mv P-P.

If that signal is not there then you would need to repeat the testing I asked you to do at the Carrier Osc board to confirm the 9vdc CW diode switching voltage is available at D1 and Q2 Buffer amp is being turned on.

I have been providing direction based on your reporting back that you have good CA-2 at Carrier board and good CA-2 at TP-5 on IF board.

If good Level at TP-5 then should have proper level at the wiper of VR-5 on the Balanced Mod. As we have discussed. No dc bias from CV and no Carrier at wiper of VR-5 then no output from the Bal Modulator.

I am pretty confident that you do have proper bias voltage from CCW to full CW on the Car Pot, but I am not certain yet that you have proper carrier output from the BM in CW mode.

Good luck.

Terry K9TW.

Dave,

I have VFO set to 14.175. With Car pot at 1200, in CW mode I get 40mV P-P in RX mode. When I flip the Send switch, the signal stays at 40 mV but it is no longer a sine wave. It is some kind of more or less sine wave with a lot of noise on it. With the Car pot at max, the noisy sinewave increases to 60 mV P-P in Send mode.

In FSK mode with Car at 1200 I get 250mV P-P in Send mode. With Car at Max I get 800 mV P-P in Send mode.

At Conn RF1-10 I get 140mV P-P in CW Send mode. I get 800mV P-P in FSK Send mode.

At the mixer output (Q1 and Q8 side of C8) I get 100 mV P-P in CW Send mode. I get 1V P-P in FSK Send mode. The signal at that point is not a sinewave but seems to have multiple signals. Probably some LO feedthrough on the mixer. The frequency counter agrees with the Kendwood readout as 14.1748 MHz.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Sorry about Q10 vs Q18. My fingers work better than what is left of my brain.

The 3 conductor plug should be positioned in forward position toward the front panel.

One thing we did not talk about is whereiyou should have the Car Level Pot set to take these measurements.

The TX Level Diagram is shown in the Service Manual. These levels were taken by Kenwood by loading the rig to approx 100 watts out at 14.175mhz and then turn the SG switch off and leave Car pot alone and Drive control alone.

Since you have no RF output in CW mode I suggest you do this for remainder of the readings:

1. VFO 14.175
2. Peak the Drive Control on receiver noise or the marker signal
3. Car Level Pot 1200
4. Heater on
5. SG switch off
6. Flip to Send to take RF drive levels

So the differences in voltages may be due to where we each have our Car Level pot set at.

Suggest you measure the voltage and frequency of the TIF signal at IF-3 Pin 2 one more time and it should be approx 250mv rms or 700mv P-P @ 8830.7mhz.

If you have close to this time to move on to the RF board. I must say this is getting a little odd as you have good output ini SSB and FSK which tells us you have good TIF level and the TX Mixer on RF Board is working which means you have good VCO (LO to the mixer).

Are you 100% certain you have no CW RF output on all bands? If so, then proceed on to the RF board with Heaters On and SG off and rig peaked as noted above.

You should have close to the values noted on the TX Level Diagram. At Conn RF-1 Pin 10 the 8.830 TIF signal level is approx 38mv rms or 108 P-P.

At output of TX Mixer should have approx 1.5v rms or 4.2v P-P rf drive at MD. At MD frequency will now be 14.175mhz transmit frequency.

If you have no RF drive or very weak at MD then need to measure the VCO level and frequency at RF-1 pin 4 and on board at TP-1. Should be close to 1.0v rms level. If no VCO try on other bands.

We are making good progress. Your Tek 2445 is perfect scope for KW Hybrid work and you apparently know how to use it and can read a schematic and can locate points on these high density boards to take measurements. This really helps.

Based on your report of no RF output in CW mode I would have thought we would have found no TIF sig at output of the IF board. TIF is not band specific and often is caused by no output from the Bal Modulator, This is why I had you start by testing for bias voltage and LO signal available. Never expected that we would be at the RF board and TX Mixer based on good RF output on other modes.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I read a little over 700mV at the drain of Q18 (actually the backside of C92 feeding the coax). I think you meant Q18 instead of Q10.

D7 and D8 are the CW switching diodes. With the mode switch in CW position, I have 2.98 volts on the anode of D7 and 2.34 volts on the cathode. I have 10.0 volts on the anode of D8 and 9.40 volts on the cathode. These voltages are there in both RX and TX, just a few 10ths of a volt lower in TX mode.

Can you confirm how the 3 pin cable ofr IF2 is supposed to plug in? It only has 3 wires but there are 5 pins on the IF board at that point. According to the chassis wiring diagram, only the first 3 pins are used as they come from S6-1.

I don't think there is anything wrong with the CW filter and the switching diodes as the CW filter works fine in RX mode.

I have 400mV P-P on Gate 1 of Q1 instead of the 160mV when flipping Send. I also have 2400mV P-P on the drain instead of 1000mV when flipping Send.

TIF signal on Conn IF-3 is 400mV P-P and the sine wave isn't quiet as clean there as it is on the drain of Q1.

Hopefully we are making progress.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Good job. Much better.

If I understand your chart you are telling me that you have approx 640mv P-P @ 8.83077 at TP-5 in CW mode with rig flipped to Send (heaters off and SG switch off). 900mv P-P is attainable by adjusting T1 on CAR-2 board, but can do later unless you want to peak it now. 640mv will work for testing.

If this is true then you have confirmed that you have the two things you need at the Balanced Mod to produce RF output from it in CW mode. 1. Offset bias voltage and 2. Proper Carrier freq and level.

From the BM output the CW signal is routed to the Crystal IF Filter and then to Q1 the Transmit IF Amp or TIF amp. TIF signal leaves the IF board and is routed to the RF board to the TX Mixer where it is mixed with VCO to produce the actual transmit rf drive signal. No TIF signal and there will be no RF drive and no RF output. Also no VCO or low VCO level and no rf drive. Lets validate that we have TIF signal in CW mode first.

Unfortunately KW didnt provide a nice test point at the output of the Balanced Mod to measure the DSBSC signal in SSB mode or the Carrier in CW mode. However, you can get on the Drain of Q10 with a hat pin or floral arrangement pin and mini-grabber test lead. If you locate the BM ring diodes D26-D29 and then output Xfmr T10 you will see Q10. It is a metal can dual gate mosfet. Looking down on the can the Drain is the upper right lead. You should read approx 800mv P-P here. This signal is routed to the Xtal filter thru switcing diodes.

Do you have the CW filter installed. It is rare but could have a bad filter. More common to have a bad switching diode.

After signal passes thru the Xtal filter it is applied to Gate 1 of TIF amp Q1. It is also a metal can dual gate mosfet and sits outside and almost between the two filters at the inboard end. Looking down on Q1 Gate 1 is at 1200. Should have approx 160mv P-P here. The Drain is at 0600 and should have approx 1000mv P-P. TIF output is on Conn IF-3 Pin 2 and should have approx 850mv P-P here. You can jump right to measuring TIF output if you want and if good then off to the RF board.

We know that you have TIF output in FSK mode as you reported good RF output in that mode. I dont kow if you keyed rig in FSK and noted the 170hz shift or not, but not important right now. Also, you should have noted that the RF output in FSK is lower as the 820 lowers the Finals Screen Grid voltage in FSK mode so the tubes plate dissipation is not exceeded in this high duty cycle mode.

That should be enough for now.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

This is what I am seeing:
TP-5 and CJ3-CA2 have the same levels in CW and FSK modes: 820mV P-P in RX mode. Flipping Send switch the level drops to 640mV P-P. I have a Tektronix 2445 Scope and have the probe in 10X to prevent loading the circuit.

Frequencies measured at CJ3-CA2:
RX mode FSK - 8.828414 - TX mode FSK 8.830620
RX mode LSB - 8.828414 - TX mode LSB 8.828579
RX mode USB - 8.831460 - TX mode USB 8.831625
RX mode CW - 8.831460 - TX mode CW 8.830777

Frequencies measured at TP-5:
RX mode FSK - 8.828410 - TX mode FSK 8.830616
RX mode LSB - 8.828410 - TX mode LSB 8.828575
RX mode USB - 8.831450 - TX mode USB 8.831622
RX mode CW - 8.831446 - TX mode CW 8.830773

I am using a Simpson 710 Frequency counter. Specs say 1 Meg input shunted by 30 pF. The slight differences in frequency readings between CJ3-CA2 and TP-5 is probably due to the cable capacitance of the cable between IF5-13 and CJ3-CA2.

I have been taking all of these measurements with the SG switch turned off and the heater switch turned off.

Ray:

I mis-spoke in Item 2 when I said you cant measure carrier at TP-5 in Rx in any of the mode switch positions. There will be legitimate carrier but not of interest.

There will be Carrier at CA-2 and TP-5 in Rx in all positions of the mode switch that you should see, but it is meaningless for CW Tx operation. It was not correct for me to label it as "Leakage" signals.

It is there by design but not for Rx or Tx operation. CA-1 Carrier Osc signals are coupled to the CAR-2 board to amp Q3 and then on to TP-5 at IF board and then sampled and sent to the CCR lead to provide carrier oscillator signals for the Counter Mixer Board. So the carrier osc signals you were measuring at each position of the mode switch in Rx are there by design to feed the counter, but of no interest to us as not utilized for the BM and CW transmit.

So you will see approx 250mv rms at 8831.50 mhz in CW and LSB and 250mv at 8828.5mhz in LSB and FSK, but not used by the BM. BM is not used in Rx operation. So disregard these signal other than the low levels you measured cannot be correct if your counter is working properly. I suspect you are not using O-scope properly. Are you using a 10X probe?

What I meant to say is at CA-2 and TP-5 the only frequency and level we care about is in CW and FSK positions of the mode switch in Tx. CA-2 carrier oscillator should be approx 250mv rms @ 8830.70mhz when in CW and FSK mode when flipped to send. This is what you are trying to validate. Measure at TP-5 in FSK as you know it is working. So use it to get your O-scope set up correctly and you can see approx 850mv P-P at 8830.7mhz. Once you can read that on your O-scope now switch to CW mode and flip to send to measure carrier osc signal level at TP-5.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Yes this new format gives me problems as well.

1. You are getting proper dc bias voltage to the BM. You need to confirm you are getting the Carrier Osc signal.

2. You cannot measure any Carrier freq or level at TP-5 in RX for any position of the mode switch. You may read some leakage signals in RX mode but meaningless. The BM is only used for TX and not RX. Only time you can measure any meaningful Carrier Osc frequency or level at TP-5 is in TX with the mode switch in CW or FSK. Carrier in RX mode is applied to another Mixer called the Product Detector and it arrives at IF board on IF-4 C1A terminal. You have separate Carrier Oscillators for RX and TX.

Also, the Car Level Pot has nothing to do with the Carrier Osc levels produced on the CAR Assembly Unit. The Car level pot unbalances the balanced modulator and determines the carrier output level from the BM.

You really need to measure CA-2 produced on the CAR-2 board. If you do not have 300mv of 8830.7mhz at TP-5 in CW mode when you flip to Send then you have to work your way back from TP-5 to CAR-2 board. CA2 can be checked on the 7th terminal up on the white terminal block on the CAR-2 board. On the IF board it comes in on Conn IF-5 pin 13.

At this point you have not confirmed that you have CAR-2 Q1 Oscillator running and available.

3. The DC voltages that you measured at D1 prove that you are getting the turn on voltages for Buffer amp Q2 so if Q1 is oscillating should get CW TX Carrier at CJ-3 and on to the IF board if all connectors are good.

You may have to adjust the frequency and output level but can talk about that later.

Suggest you buy a Freq Counter. Can measure Freq roughly with O-scope. Some measure and display Freq (may or may not do so accurately) and some require using F=1/T and not accurate enough for adjusting the Oscillators in the KW hybrids.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Let's try this again. For some reason yahoo has been mangling my posts. This has been a problem ever since they went to this new stupid format they are using.

Measuring at TP-2 the voltage varies from 16 mV to .443V when adjusting the CAR control in both FSK and CW mode. On Conn IF-5 at the CV terminal, the voltage varies from .12V to 8.95V in both FSK and CW mode when adjusting the CAR control.

Also, on the FIX VOX board FIX3-11 is grounded with no key plugged in. Plugging a key in, FIX3-11 follows the key (open key up, grounded key down).

I have cleaned the contacts on the Mode switch and checked for broken wires.

At TP-5 I measure 8.831434 MHz at .64V P-P (on scope) in all positions of the mode switch without the Send switch flipped. When I flip the Send switch the voltage drops to .48V P-P. The CAR control has no affect on the signal level with the Send switch in either position.

I measure 8.97V at the CW terminal on CAR-2 when I flip the Send switch. I measure 8.94V at the anode of D1 and 8.19V at the cathode when the Send switch is flipped.

I have a couple of multimeters, a 150 MHz analog scope, 100 MHz digital scope, W7ZOI power meter, and a KA7EXM power meter. I feel comfortable taking measurements anywhere inside the radio including the Final Cage.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

For some reason I cannot read your entire response? It appears you are reporting back that you have good bias voltage available at the BM from the Car Pot. In CW TX mode you need this bias voltage and you need the local oscillator (LO) or Carrier to produce an output. Which in this case it is 8.830.70mhz CA-2 produced on the CAR-2 Unit.

You are getting CA-2 Carrier in FSK mode so it tells me the Crystal and the soldering at its pins have to be good.

If you have a RF millivolt meter or O-scope you can measure the 8830.7 mhz Carrier at the IF board at TP-5.TP-5 is tucked back in the corner under the chassis side rail. With rig in CW mode flip to send and measure the level and the frequency at TP-5. It should be approx 300mv rms or approx 850mv P-P on a scope at 8830.70mhz.

I would measure the level first before you look at it with a Freq Counter as the counter may pull the level down. If you dont have a means to measure CA-2 Carrier level and frequency then at minimum measure CW terminal at CAR-2 Unit board to make sure you are getting CW TX bias voltage.

If you remove the 2 screws that secure the cover you will see a white 10 pin connector. The 3rd pin from the Crystal is the CW terminal. When you flip to send in CW mode should see approx 9.0vdc here. If you have 9vdc and still no output then suspect bad switching diode D1. D1 is close to the Crystal and you can measure the voltage at its anode and cathode. When you flip to send in CW mode should read approx 9vdc on the anode and approx 8.3vdc on the cathode. Note: The 9vdc will depend on where the AVR regulated 9vdc has been set too.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray

I forgot to mention where I am going with this (if not obvious) is a bad/dirty Mode switch contact or a broken wire at the mode switch in CW mode. The fact that you have output in FSK tells me that you do have approx 0.0 to 0.60vdc at TP-2 which then means the path from CV to the BM is good.

If you have no DMM, VOM, or VTVM the mode switch in a TS820 is an open deck type and pretty accessible with bottom cover off so you should be able to apply some deoxit and canned air to clean the contacts.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK well that would have been a quick fix and not first time so had to ask.

What test gear do you have and what is your comfort level to take measurements inside the rig?

When you inject audio into mic line and get output it tells you that your Balanced Modulator is working. In CW mode to produce output from the BM the Car Pot provides variable DC voltage to bias on the ring diodes. It is derives this bias voltage from regulated 9vdc from AVR board thru mode switch contacts.

The BM is on the IF board. Need to measure at Conn IF-5 at the CV terminal. Should see variable 0 to 9vdc at CV as you adjust the Car Pot thru its range.

Then measure at TP-2 and should see approx 0.0 to 0.70vdc as you adjust the Car Pot.

Ray:

Do you have a key in the key jack? If so remove it or key the key with Car Pot advanced. Cant load rig in CW mode if you have a key in key jack and it isnt closed. Brings back memories of the J-38 slider bar.

We can talk about plate dip not occurring at right place when we get CW working.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

Thanks for the comments.

1) I have 60 ma of current when I flip Send switch in CW, USB, and LSB modes. I don't have a microphone as I only operated CW back when I was on the air. I have a 1KHz tone generator and connected it to the microphone input. When I do this and increase MIC control in both USB and LSB I am able to drive plate current to the same 160 ma (on 20 meters) that I get in the FSK mode. So it appears CW is the only mode that isn't functioning.

2) I tuned the rig to the max power out (IP 160 ma) into the dummy load in the FSK position. I then switch to CW mode but the IP stays at 60 ma. This is with the CAR control at max (10 mark). Bias voltage drops from -100 to -63 volts when I flip Send switch in CW mode.

3) In the FSK mode I get almost FSD with CAR control at max on 20 meters in the ALC position. I am only 2 tick marks away from FSD. On 80, 40, and 160 I am able to get FSD at lower levels of the CAR control. However, when I turn SG back on and tune, the plate dip is in the wrong position for 40 and 160. For both of those bands max dip is at the very low end of 3.5 dial marking. On 20, 15, and 10 the dip is in the correct position. On 10 I am only able to get 80 ma of plate current at min dip with CAR at max. This does indicate the 12BY7 is bad. I think I have a spare one somewhere around here - just have to look. When I switch to USB or LSB I am able to get the same levels of ALC deflection as FSK when I inject the 1 KHz. However, in CW mode I do not get any ALC meter deflection.

4) I will perform this step once the rig is working.

5) I am using the dummy load because I have a 40 meter dipole 8 feet off the ground (HOA) as my only antenna and not sure of the impedance it reflects. I have a Heath HM-15 SWR bridge but it doesn't have a watts reading. I just received an order from Mouser yesterday with the parts to build the dummy load that is on the K4EAA website. I am including the power measurement components so I will be able to know what my power out is. Once I am back on the air I will obtain an inline watt meter.

6) I haven't been on the air in 17 years and am wanting to get back on since I will be retiring in Jan and moving to somewhere that doesn't have a HOA. I have a HW-100 and a FT-101E that have sat in the garage for the last 17 years. I built the HW-100 back in 1968 and last used it in 1986. The FT-101 was working and I was using it on a daily basis when I went QRT at the end 1996. I bought this TS-820 10 years ago but have never used it. It has sat in the closet in my office since I bought it. I figured I would try to get it working first as it hasn't been exposed to extreme temperatures. I would be scared to power the other two up without replacing all the power supply caps first. My garage never drops below 100 four months out of the year.

AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

1. In LSB/USB should be 60ma resting plate current when you flip to send or key the mic. No indication on RF meter position until you modulate the rig (speak in mic). Can you see and adjust the resting plate current in SSB mode?

2. In Tune/CW will be plate current when you have RF drive (Car Pot advanced) only if you have RF drive as indicated by peaking the ALC indication with the Drive control.

Are you certain that Aux and TR relays are keying when you flip to send or key the mic? Sounds like they are based on seeing tube voltage dropping. Bias voltage at Finals control grid better not be dropping only 10%. It should change from approx -100vdc cutoff bias to approx -55vdc operating bias. If not then plate current and no RF output.

3. You can try a new 12BY7A as easy to do, but your rig has the diagnostic meter you need. Turn off SG switch and place rig in CW mode and peak the ALC indication by advancing the Car pot. Should be able to get full scale meter deflection (FSD) and hold there a few

seconds on each band without the ALC indication falling off. Should get FSD with Car Pot advanced no more than approx 1000 to 1100. Rest between each band test as Driver tube is running class A (full plate current).

4 If RF detector is pegging at 70ma plate current then turn down the sensitivity pot. You always have to adjust the sensitivity pot. Set it for approx 2/3 deflection at 100 watts out. Would have been handy if KW would have put the pot on the front panel. They provided this meter position as it is better to load a Class AB1 linear amp by tuning for max rf output without exceeding plate dissipation than using the old dip and load method. They also provided it as external wattmeters were not common and they wanted the radio to be instrumented to be stand alone.

5. I would not use a 50 watt dummy load. If you must then have to realize all dummy loads have a duty cycle. Can use it but have to limit key down time.

6. When you get a couple of bucks ahead suggest you get an external wattmeter. Makes a good Loading aid and a good diagnostic tool. Drake W4, Heath HM-102, any of the MFJs are good and give you a SWR bridge and Wattmeter in one piece of test gear. Having actual output wattage tells you a lot more than looking at relative RF output power by measuring rf voltage at SO-239 or measuring the temperature of your dummy load.

I have a Kenwood TS-820S. Receive is working fine. Strange transmit problem.

When the Mode switch is the Tune, CW, USB, or LSB postion and I operate the Send switch I get no plate current and no output. When the switch is in the FSK position, I get almost normal plate current and can tune the rig to about 3/4 full power out. I can only get the load and plate controls to 160 ma into my dummy load with carrier control at max. Maybe a bad 12BY7 preventing full power out.

The other strange thing is when the meter switch is in the RF position, I can only increase the carrier control to about 70 ma plate current before the meter pegs when in FSK mode.

My 50 watt dummy load doesn't have a power indicator but I know the transmitter is putting out decent power in FSK mode as the resistors in the dummy load are getting warm.

Voltages (SG, Plate, Bias) are all normal. They drop about 10% when switching from receive to transmit mode. This drop happens in all postions of the mode switch, not just the FSK mode.

This makes no sense as in most cases the Tune and CW contacts of S6 are tied together. And S6-2 ties Tune, CW, and FSK together. Has anyone seen this issue before or give me an idea where to look for the problem?

Please to clarify??

"140 milliAmperes Volts Alternating Current" ?????

One or the other. (milli-)Amperes, or Volts. Which?

Do you mean the tube CURRENT is 140 mA? Or that the tube VOLTAGE drops from 12 Volts AC no-load, to 140 thousandths of one VOLT??

Are you measuring from Pin 2 to chassis ground?

To measure the current, you would need to have LIFTED or broken the wire onto Pin 2 and insered the Ammeter into the circuit, one lead to the lifted wire, the other to the Pin 2 terminal.

For voltage, from Pin 2 with one lead, ground with the other lead, to measure the voltage drop when the heater is turned on.

What sort of meter are you using, by the way? An old-fashioned VTVM? Or a modern DMM? (Won't make a lot of difference, either way, for measuring heater voltage, just curious.) Or are you actually measuring current, using an Ameter or milliAmmeter?

From: <bvelasquez@...>
Topic: 45399 Message: 45421

OK, everyone. Here is a summary of what I'm seeing, and I believe I found the problem.

With the tubes in, I see the following:

Finals Board:

120mv on Pin 2 on V1 with HT switch ON.
50.2mv on Pin 7 on V1

RF Board

300mv on Pin 5 with HT switch ON

The HT switch does toggle power ON and OFF when you flip it.

However, when hooking up the probes and running through the tests, the driver filaments and the 6146 filaments lit up!! What?? I measured the voltage and all was as it should be 12 VAC at Pin 2 on V1 and the same on the RF board pin 5. So good power and filaments lit.

I toggled the HT switch OFF and back ON, back to the problem. No 12 VAC.

So, I suspect it is the HT switch, because if I keep toggling it ON and OFF, the voltage eventually comes back and the filaments are lit. Dirty HT switch contacts causing poor connection to 12 VAC power supply possibly?

I'll look further.

Again, thank you for all your help! Any suggestions on how to clean or check the HT switch would be greatly appreciated.

Barry

---In ts-520_820_530_830@yahoogroups.com, <w5rkl@...> wrote:

Brad,

If you took my response as "biting you head off" then you took it wrong.

I am sorry Brad but I do not agree with the switch being intermittent. There is no evidence, at least at this stage, that indicates the switch is intermittent. The presence of 12VAC at pin 2 of V1 final tube indicates the switch is not bad or even intermittent. An intermittent switch could easily show the filaments lit then dying out without touching the switch but that has not been indicated.

Your wording of your response about the filament voltage to the final tube indicated to me that you thought the final tube filament voltage should be 6.3VAC not 12VAC. I am aware the filament voltage for the 6146 is 6.3VAC but the 6146 filaments, as I said, in the 820 are wired in series so the filament voltage in the 820 will be 12VAC. Your indication of the 6146 filament wiring was not clear, you hinted that the final tubes were in series, which

they are.

I don't mean any disrespect to anyone but it gets very frustrating and annoying when trying to help someone and they don't listen. They ask for help yet when given a few simple easy steps to take, they don't follow or if they do they do other things they are not told to do which quite often confuses the issue! That happens a lot on this and other ham forums and groups and it gets very frustrating and annoying!

Also, members need to read an entire thread before responding. It's quite possible that your response could duplicate a response given a few hours or half a day earlier.

Mike W5RKL

On 10/23/2013 8:59 AM, Brad Allen wrote:

Mike, I said the switch could be bad because of the 140ma VAC reading. Obviously someone read something wrong. The filaments of the 6146's are in series with 12 volts which that means 6VAC at each filament. !2 volts AC would go to the 12BY7. So the12BY7 is in PARALLEL with 2 6146's in series and voltage across each supplied to the tubes. No, I did not read the whole thread. It seems that some don't want to get all the spaces and such on their portable devices, so some stuff is cutoff. I usually look at the last response. After I saw the 140ma VAC reading I was not sure what kind of know how you had, so I attempted the simple and easy route. I know what the schematic says without looking at it and I NEVER said the voltage to the tubes was 6 VAC. I said it was 12VAC so there should be 6 VAC across EACH tube in the final cage. The 12BY7 would be 12 volts. You asked for help in this, and I responded in good faith. No reason to be so quick to bite off my head. The switch could be intermittent or where the contacts can't handle the current. If you say the switch is not bad, OK, just say so. I am only trying to help you get you through a simple series parallel circuit.
Oh by the way, 2 6146's in SERIES with 12 volts applied would put 6 volts at each filament. That is a true statement. The driver is fed across the transformer with 12 volts. I will let you read what you wrote and analyze that again. I never said the TOTAL voltage across two 6146's is 6VAC, you did. I said ONE tube is 6VAC so the tubes may be in series which would equal the 12 VAC applied. Brad KB2CHY

. I believe the voltage to a 6146 should be 6.3 volts, not 12 volts. Please READ what I wrote. You will see I said to "A" 6146, not both.

Subject: Re: [TS-520_820_530_830] RE: Transmitter not working - No idling current, tubes not turning on.

NO the switch is NOT bad! Did you read the entire thread? It has already been determined that 12VAC IS present at pin 2 of final tube V1 (see below) so the switch can't be bad so why suggest it is!!!

"I checked filament voltage at pin 2 of V1, the 6146B. It's at 12VAC without the tubes inserted, as it should be."

You believe the 820 filament voltage to the 6146 filaments should be 6VAC? Why would you say that when the final tube filaments are wired in "series"? That would put "3VAC" across each final tube filament!! If you look at the 820 schematic you will clearly see that the final tube filaments are, in fact, wired in "series" AND the driver and both final tube filament voltage IS "12VAC" not "6VAC" as you thought!

Mike W5RKL

On 10/23/2013 7:52 AM, Brad Allen wrote:

How can the voltage be 140ma VAC? Your issue is a simple one. No need to check high voltage or alignment of the radio. I believe the voltage to a 6146 should be 6.3 volts, not 12 volts for one thing and I also believe that the two tubes may be in series. Try checking the RESISTANCE of the filaments of each tube. Do you have a schematic? You may want to trace right back to the transformer. You may have something as simple as a bad switch, quite common for those to go bad. Brad KB2CHY

Subject: [TS-520_820_530_830] RE: Transmitter not working - No idling current, tubes not turning on.

Some more information to the group. I checked filament voltage at pin 2 on V1, the 6146B. It's at 12 VAC without the tubes inserted, as it should be. However, with the tubes in, the voltage is at 140ma VAC. I would imagine it should stay at 12 VAC. I checked the HV, and the tubes are at 930 V when power is on. The driver tube filaments are also not on when the HT switch is ON.

I checked the cathode resistors and they show 5 OHMS to ground.

I'm wondering why the filament voltage is dropping like that, is this normal?

---In TS-520_820_530_830@yahoogroups.com mailto:TS-520_820_530_830@yahoogroups.com , <ts-520_820_530_830@yahoogroups.com> mailto:ts-520_820_530_830@yahoogroups.com wrote:
Hello, recently acquired a TS-820. The receive works great.

However, when attempting the Tuning procedure (Checking that all controls are set according to the manual), the ALC meter did not move at the first step. I checked the Idling current and it stays at zero. Removing the cover, I checked to see if the filaments on the 6164B's light up with the H. Switch on. They do not light up.

With HV set on the meter, I do read a little over 9 on the scale.

Where are some common places that would exhibit these symptoms in the transmitter portion of the radio so that I have a starting point on what to check. Do I check if the SG switch is functional, H. Switch? Ex ternal VFO cable is good. I checked that and all pins have continuity.

Any other starting bases begin troubleshooting?

Thank you!

Hello Mike,

Thank you for the help with this. The switch does seem to be intermittent. In performing all the tests suggested here, I noticed at one point the filaments did light up WITH the tubes in. There was 12 VAC at Pin 2 on V1 at that point. However, if I turn of the HT switch and turn it back on, the voltage would then be at 140mv at pin 2 on V1. Same issue at the driver tube, pin 5. A mv range with no filaments lit. However, repeatedly toggling the HT switch will eventually provide the correct voltage at pin 2 on V1 at the finals and pin 5 at the RF board. So, unless there is something else that could cause this behavior along the path from the HT switch to these pins, the HT switch might be dirty or something else.

I'm looking for any suggestions on what else to check in this case of intermittent behavior besides the HT switch, which I will check closely and clean.

The 12 VAC seems to be reliably at the pins when the tubes are removed, but that could have been a fluke and the HT switch was working, by chance, at those times. I'll have to check all this again and see with and without the tubes to see if the 12VAC comes and goes.

73,

Barry

Ugh.. why are none of my posts getting posted!!! I'm trying to correct my mistake of using mA instead of mV. My mistake, but for whatever reason, none of my correcting posts are making it on this thread. Does someone have to approve each response?? I've responded hours ago to correct the mistake, but I don't see a single one of my posts.

The Heater switch is faulty it seems. Toggling it repeatedly eventually provides the correct voltages. Toggling it some more does not. It's intermittent. When it works, all voltages are good.

I'll get some Deoxit and clean the switch and see if that helps. Hope this response gets into this thread.

Barry

Tovarishch, the problem is the mixed terms you used here. Nobody is
trying to snipe at you, we are just confused as all get-out as to what
you could POSSIBLY mean.

You used, as it shows above, the term

140 MILLI-AMPERES VOLTS ALTERNATING CURRENT

when I expand all the abbreviations.

Milli-amperes are NOT Volts. You measure them in totally different
ways, for one thing, with totally different meters. (Can be combined
into one box, certainly, but an ammeter is placed in series with the
circuit under test, and volts are measured with the meter in parallel to

the part being checked.)

Is the correct unit MILLIVOLTS, perhaps??? Abbreviated "mV" ?? Because milli-Ampere Volts is TRULY confusing.

You should get 12 Volts AC from Pin 2 of V1 to chassis ground, and only 6 Volts AC at pin 7 of V1 (which is connected directly to pin 2 of V2, the other 6146 tube; it is just the other end of the same wire).

Heater switch ON of course. Flip it to OFF and that should drop to Zero volts. It might be worth a check, this will make certain you don't have a wonky heater switch; they do go out of order sometimes.

Really, it's not a personal attack. We just want to figure out what Milli-Amperes Volts really meant.

My apologies to everyone in this thread for mis-labelling "140ma VAC". It's 140 mv!! NOT ma. Ugh. My big mistake and again I apologies for not double-checking what I was typing and verifying the labeling I was giving you all.

There is 12 VAC on V1, pin 2 *without* the V1 tube in place. With the tube, it's 140mv +-10mv. My meter will not settle. I will check the filament voltages on the driver tube next.

I just wanted to clarify the ma/mv confusion as quickly as possible as when you guys pointed out my labeling mistake I new that couldn't be right and had to get the correct information to you soon.

This is BASIC electricity/electronics knowledge that ALL hams should know how to do. However, unfortunately many members don't believe they need to know this stuff so we end up with how this thread has gone!

Tackling one problem at a time is what should be done. Once the filament issue is solved I suspect the loss of 60ma idling current will no longer exist.

Subject: Re: [TS-520_820_530_830] RE: Transmitter not working - No idling current, tubes not turning on.

The original questioner said â□□the 820 filament voltage to the 6146 filaments should be 6VACâ□□. I suspect that what he meant was â□□the 820 filament voltage across each of the 6146 filaments should be 6Vacâ□□ which would be correct. I think itâ□□s a case of using an ambiguous form of words rather than a misapprehension that 6146 valves have a 3V filament.

Like everyone else, I am at loss to see where 140ma VAC comes from, even if 140ma, 140 mVAC or 140VAC was meant.

Guy â□□G3POM

On 10/23/2013 7:52 AM, Brad Allen wrote:

How can the voltage be 140ma VAC? Your issue is a simple one. No need to check high voltage or alignment of the radio. I believe the voltage to a 646 should be 6.3 volts, not 2 volts for one thing and I also believe that the two tubes may be in series. Try checking the RESISTANCE of the filaments of each tube. Do you have a schematic? You may want to trace right back to the transformer. You may have something as simple as a bad switch, quite common for those to go bad. Brad KB2CHY

Subject: [TS-520_820_530_830] RE: Transmitter not working - No idling current, tubes not turning on.

Some more information to the group. I checked filament voltage at pin 2 on V1, the 6146B. It's at 12 VAC without the tubes inserted, as it should be. However, with the tubes in, the voltage is at 140ma VAC. I would imagine it should stay at 12 VAC. I checked the HV, and the tubes are at 930 V when power is on. The driver tube filaments are also not on when the HT switch is ON.

I checked the cathode resistors and they show 5 OHMS to ground.

I'm wondering why the filament voltage is dropping like that, is this normal?

---In TS-520_820_530_830@yahoogroups.com mailto:TS-520_820_530_830@yahoogroups.com, mailto:ts-520_820_530_830@yahoogroups.com mailto:ts-520_820_530_830@yahoogroups.com wrote:

Hello, recently acquired a TS-820. The receive works great.

However, when attempting the Tuning procedure (Checking that all controls are set according to the manual), the ALC meter did not move at the first step. I checked the Idling current and it stays at zero. Removing the cover, I checked to see if the filaments on the 6164B's light up with the H. Switch on. They do not light up.

With HV set on the meter, I do read a little over 9 on the scale.

Where are some common places that would exhibit these symptoms in the transmitter portion of the radio so that I have a starting point on what to check. Do I check if the SG switch is functional, H. Switch? Ex ternal VFO cable is good. I checked that and all pins have continuity.

Any other starting bases begin troubleshooting?

Thank you!

Quick query what are you measuring as 140mA VAC???
If your filaments are open then you should measure 12 volts ac across one and nothing across the other.
There is one possibility though. Remove the 6146B's (after temporarily grounding the plate connector) to ensure safety and measure the resistance between pins 2 and 7, 1 pin away from the locating lug. It should be a few Ohms. If so your heaters are OK.
Then check between pin 1 and pin 2. It should be very high.
If not you may have a heater/cathode short. In either case new 6146B's are the only answer.
The only other possibility is a crack in the final circuit board (look VERY closely) or a dry joint in the heater circuit on the board. This can happen as there is quite a lot of heat around given the poor efficiency of the 820 series finals on some bands. Once again an Ohmmeter is what you need to locate it together with careful inspection.
Hope these suggestions help.

Thanks Terry. I have been talking to you since you have been helping. I don't know what made me put Dave on the last message (old age maybe).

I decided to start over from the beginning and go stage by stage this afternoon. This is what I did:
(All measurements taken with Send switch operated and Mode switch in CW position. Also, the measurements are the same in both CW and FSK modes.)

I suspected D1 or L1 was bad on the CAR-II board was bad but that is not the case. I have 720mV on CA2 leaving the CAR-II board in both CW and FSK send modes. I also have 720mV P-P on CA2 (IF5-13) on the IF board. I have 100mV P-P at the coax that connects to C92 on the IF board. On the other end of that coax where it connects to the top of T4 on the IF board I also have 100mV P-P. I would have thought the signal out of Q18 would have been stronger but maybe not.

I have 340mV at the junction of the cathode of D7 and C14 on the IF board. I have 280mV on the side of C14 where it feeds the CW filter. The signal going into the filter measures 8.830755 MHz. I only have 6mV P-P coming out of the crystal filter. Is the crystal filter used for transmit?

I connected the antenna to the radio and 20 meters is open. Tuning in CW signals in USB mode and switching to CW mode drops the signal by about 1 S-Unit when the signal is peaked for max signal in both modes.

Where do I go from here?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Are you talking Dave or Terry ? If someone is helping you off list I can back away as I have a pretty full plate right now.

I am not clear where you are measuring this 40mv P-P signal at?

Before I go I will mention that it is normal to not have a clean sine wave at TIF. It does have harmonic content and it is as you say due to LO mixing action. In this case it is coming from the VCO signal feeding back from the TX Mixer on RF board to the IF board.

This is easy to confirm with a TS-830 as you can easily unplug the VCO cable from the PLL board and the TIF signal will then be a nice clean 8.830mhz sine wave.

Dont worry about the complex waveform. Should still be able to get a reasonably close TIF measurement. It may not match exactly the levels on the TX Level Diagram,but you can compare it to the level you get with FSK carrier oscillator.

I dont use a O-scope to run TX Level diagrams once I get to the output of the TIF amp. I use a Boonton RF Millivolt meter and measure levels in rms and the "dirty" TIF signal

presents no problem.

I have a new digital O-scope and it has a variety of digital filters. If I set it for a LP filter with a roll off frequency of 10mhz I can get a pretty clean 8.830 TIF sine wave display.

I dont know the Tek 2445 capability in this regard.

One final reminder is that good TIF signal level of approx 38mv rms or 107mv P-P is based on the premise that you accurately measured CA2 at the iF board of approx 300mv rms or 850mv P-P.

If that signal is not there then you would need to repeat the testing I asked you to do at the Carrier Osc board to confirm the 9vdc CW diode switching voltage is available at D1 and Q2 Buffer amp is being turned on.

I have been providing direction based on your reporting back that you have good CA-2 at Carrier board and good CA-2 at TP-5 on IF board.

If good Level at TP-5 then should have proper level at the wiper of VR-5 on the Balanced Mod. As we have discussed. No dc bias from CV and no Carrier at wiper of VR-5 then no output from the Bal Modulator.

I am pretty confident that you do have proper bias voltage from CCW to full CW on the Car Pot, but I am not certain yet that you have proper carrier output from the BM in CW mode.

Good luck.

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Dave,

I have VFO set to 14.175. With Car pot at 1200, in CW mode I get 40mV P-P in RX mode. When I flip the Send switch, the signal stays at 40 mV but it is no longer a sine wave. It is some kind of more or less sine wave with a lot of noise on it. With the Car pot at max, the noisy sinewave increases to 60 mV P-P in Send mode.

In FSK mode with Car at 1200 I get 250mV P-P in Send mode. With Car at Max I get 800 mV P-P in Send mode.

At Conn RF1-10 I get 140mV P-P in CW Send mode. I get 800mV P-P in FSK Send mode.

At the mixer output (Q1 and Q8 side of C8) I get 100 mV P-P in CW Send mode. I get 1V P-P in FSK Send mode. The signal at that point is not a sinewave but seems to have multiple signals. Probably some LO feedthrough on the mixer. The frequency counter agrees with the Kendwood readout as 14.1748 MHz.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Sorry about Q10 vs Q18. My fingers work better than what is left of my brain.

The 3 conductor plug should be positioned in forward position toward the front panel.

One thing we did not talk about is whereiyou should have the Car Level Pot set to take these measurements.

The TX Level Diagram is shown in the Service Manual. These levels were taken by Kenwood by loading the rig to approx 100 watts out at 14.175mhz and then turn the SG switch off and leave Car pot alone and Drive control alone.

Since you have no RF output in CW mode I suggest you do this for remainder of the readings:

1. VFO 14.175
2. Peak the Drive Control on receiver noise or the marker signal
3. Car Level Pot 1200
4. Heater on
5. SG switch off
6. Flip to Send to take RF drive levels

So the differences in voltages may be due to where we each have our Car Level pot set at.

Suggest you measure the voltage and frequency of the TIF signal at IF-3 Pin 2 one more time and it should be approx 250mv rms or 700mv P-P @ 8830.7mhz.

If you have close to this time to move on to the RF board. I must say this is getting a little odd as you have good output ini SSB and FSK which tells us you have good TIF level and the TX Mixer on RF Board is working which means you have good VCO (LO to the mixer).

Are you 100% certain you have no CW RF output on all bands? If so, then proceed on to the RF board with Heaters On and SG off and rig peaked as noted above.

You should have close to the values noted on the TX Level Diagram. At Conn RF-1 Pin 10 the 8.830 TIF signal level is approx 38mv rms or 108 P-P.

At output of TX Mixer should have approx 1.5v rms or 4.2v P-P rf drive at MD. At MD frequency will now be 14.175mhz transmit frequency.

If you have no RF drive or very weak at MD then need to measure the VCO level and frequency at RF-1 pin 4 and on board at TP-1. Should be close to 1.0v rms level. If no VCO try on other bands.

We are making good progress. Your Tek 2445 is perfect scope for KW Hybrid work and you apparently know how to use it and can read a schematic and can locate points on these high density boards to take measurements. This really helps.

Based on your report of no RF output in CW mode I would have thought we would have found no TIF sig at output of the IF board. TIF is not band specific and often is caused by no output from the Bal Modulator, This is why I had you start by testing for bias voltage and LO signal available. Never expected that we would be at the RF board and TX Mixer based on good RF output on other modes.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I read a little over 700mV at the drain of Q18 (actually the backside of C92 feeding the coax). I think you meant Q18 instead of Q10.

D7 and D8 are the CW switching diodes. With the mode switch in CW position, I have 2.98 volts on the anode of D7 and 2.34 volts on the cathode. I have 10.0 volts on the anode of D8 and 9.40 volts on the cathode. These voltages are there in both RX and TX, just a few 10ths of a volt lower in TX mode.

Can you confirm how the 3 pin cable ofr IF2 is supposed to plug in? It only has 3 wires but there are 5 pins on the IF board at that point. According to the chassis wiring diagram, only the first 3 pins are used as they come from S6-1.

I don't think there is anything wrong with the CW filter and the switching diodes as the CW filter works fine in RX mode.

I have 400mV P-P on Gate 1 of Q1 instead of the 160mV when flipping Send. I also have 2400mV P-P on the drain instead of 1000mV when flipping Send.

TIF signal on Conn IF-3 is 400mV P-P and the sine wave isn't quiet as clean there as it is on the drain of Q1.

Hopefully we are making progress.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Good job. Much better.

If I understand your chart you are telling me that you have approx 640mv P-P @ 8.83077 at TP-5 in CW mode with rig flipped to Send (heaters off and SG switch off). 900mv P-P is attainable by adjusting T1 on CAR-2 board, but can do later unless you want to peak it now. 640mv will work for testing.

If this is true then you have confirmed that you have the two things you need at the Balanced Mod to produce RF output from it in CW mode. 1. Offset bias voltage and 2. Proper Carrier freq and level.

From the BM output the CW signal is routed to the Crystal IF Filter and then to Q1 the Transmit IF Amp or TIF amp. TIF signal leaves the IF board and is routed to the RF board to the TX Mixer where it is mixed with VCO to produce the actual transmit rf drive signal. No TIF signal and there will be no RF drive and no RF output. Also no VCO or low VCO level and no rf drive. Lets validate that we have TIF signal in CW mode first.

Unfortunately KW didnt provide a nice test point at the output of the Balanced Mod to measure the DSBSC signal in SSB mode or the Carrier in CW mode. However, you can get on the Drain of Q10 with a hat pin or floral arrangement pin and mini-grabber test lead. If you locate the BM ring diodes D26-D29 and then output Xfmr T10 you will see Q10. It is a metal can dual gate mosfet. Looking down on the can the Drain is the upper right lead. You should read approx 800mv P-P here. This signal is routed to the Xtal filter thru switcing diodes.

Do you have the CW filter installed. It is rare but could have a bad filter. More common to have a bad switching diode.

After signal passes thru the Xtal filter it is applied to Gate 1 of TIF amp Q1. It is also a metal can dual gate mosfet and sits outside and almost between the two filters at the inboard end. Looking down on Q1 Gate 1 is at 1200. Should have approx 160mv P-P here. The Drain is at 0600 and should have approx 1000mv P-P. TIF output is on Conn IF-3 Pin 2 and should have approx 850mv P-P here. You can jump right to measuring TIF output if you want and if good then off to the RF board.

We know that you have TIF output in FSK mode as you reported good RF output in that mode. I dont kow if you keyed rig in FSK and noted the 170hz shift or not, but not important right now. Also, you should have noted that the RF output in FSK is lower as the 820 lowers the Finals Screen Grid voltage in FSK mode so the tubes plate dissipation is not exceeded in this high duty cycle mode.

That should be enough for now.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

This is what I am seeing:
TP-5 and CJ3-CA2 have the same levels in CW and FSK modes: 820mV P-P in RX mode. Flipping Send switch the level drops to 640mV P-P. I have a Tektronix 2445 Scope and have the probe in 10X to prevent loading the circuit.

Frequencies measured at CJ3-CA2:
RX mode FSK - 8.828414 - TX mode FSK 8.830620
RX mode LSB - 8.828414 - TX mode LSB 8.828579
RX mode USB - 8.831460 - TX mode USB 8.831625
RX mode CW - 8.831460 - TX mode CW 8.830777

Frequencies measured at TP-5:
RX mode FSK - 8.828410 - TX mode FSK 8.830616
RX mode LSB - 8.828410 - TX mode LSB 8.828575
RX mode USB - 8.831450 - TX mode USB 8.831622
RX mode CW - 8.831446 - TX mode CW 8.830773

I am using a Simpson 710 Frequency counter. Specs say 1 Meg input shunted by 30 pF. The slight differences in frequency readings between CJ3-CA2 and TP-5 is probably due to the cable capacitance of the cable between IF5-13 and CJ3-CA2.

I have been taking all of these measurements with the SG switch turned off and the heater switch turned off.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

I mis-spoke in Item 2 when I said you cant measure carrier at TP-5 in Rx in any of the mode switch positions. There will be legitimate carrier but not of interest.

There will be Carrier at CA-2 and TP-5 in Rx in all positions of the mode switch that you should see, but it is meaningless for CW Tx operation. It was not correct for me to label it as "Leakage" signals.

It is there by design but not for Rx or Tx operation. CA-1 Carrier Osc signals are coupled to the CAR-2 board to amp Q3 and then on to TP-5 at IF board and then sampled and sent to the CCR lead to provide carrier oscillator signals for the Counter Mixer Board. So the carrier osc signals you were measuring at each position of the mode switch in Rx are there by design to feed the counter, but of no interest to us as not utilized for the BM and CW transmit.

So you will see approx 250mv rms at 8831.50 mhz in CW and LSB and 250mv at 8828.5mhz in LSB and FSK, but not used by the BM. BM is not used in Rx operation. So disregard these signal other than the low levels you measured cannot be correct if your counter is working properly. I suspect you are not using O-scope properly. Are you using a 10X probe?

What I meant to say is at CA-2 and TP-5 the only frequency and level we care about is in CW and FSK positions of the mode switch in Tx. CA-2 carrier oscillator should be approx 250mv rms @ 8830.70mhz when in CW and FSK mode when flipped to send. This is what you are trying to validate. Measure at TP-5 in FSK as you know it is working. So use it to get your O-scope set up correctly and you can see approx 850mv P-P at 8830.7mhz. Once you can read that on your O-scope now switch to CW mode and flip to send to measure carrier osc signal level at TP-5.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Yes this new format gives me problems as well.

1. You are getting proper dc bias voltage to the BM. You need to confirm you are getting the Carrier Osc signal.

2. You cannot measure any Carrier freq or level at TP-5 in RX for any position of the mode switch. You may read some leakage signals in RX mode but meaningless. The BM is only used for TX and not RX. Only time you can measure any meaningful Carrier Osc frequency or level at TP-5 is in TX with the mode switch in CW or FSK. Carrier in RX mode is applied to another Mixer called the Product Detector and it arrives at IF board on IF-4 C1A terminal. You have separate Carrier Oscillators for RX and TX.

Also, the Car Level Pot has nothing to do with the Carrier Osc levels produced on the CAR Assembly Unit. The Car level pot unbalances the balanced modulator and determines the carrier output level from the BM.

You really need to measure CA-2 produced on the CAR-2 board. If you do not have 300mv of 8830.7mhz at TP-5 in CW mode when you flip to Send then you have to work your way back from TP-5 to CAR-2 board. CA2 can be checked on the 7th terminal up on the white terminal block on the CAR-2 board. On the IF board it comes in on Conn IF-5 pin 13.

At this point you have not confirmed that you have CAR-2 Q1 Oscillator running and available.

3. The DC voltages that you measured at D1 prove that you are getting the turn on voltages for Buffer amp Q2 so if Q1 is oscillating should get CW TX Carrier at CJ-3 and on to the IF board if all connectors are good.

You may have to adjust the frequency and output level but can talk about that later.

Suggest you buy a Freq Counter. Can measure Freq roughly with O-scope. Some measure and display Freq (may or may not do so accurately) and some require using F=1/T and not accurate enough for adjusting the Oscillators in the KW hybrids.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Let's try this again. For some reason yahoo has been mangling my posts. This has been a problem ever since they went to this new stupid format they are using.

Measuring at TP-2 the voltage varies from 16 mV to .443V when adjusting the CAR control in both FSK and CW mode. On Conn IF-5 at the CV terminal, the voltage varies from .12V to 8.95V in both FSK and CW mode when adjusting the CAR control.

Also, on the FIX VOX board FIX3-11 is grounded with no key plugged in. Plugging a key in, FIX3-11 follows the key (open key up, grounded key down).

I have cleaned the contacts on the Mode switch and checked for broken wires.

At TP-5 I measure 8.831434 MHz at .64V P-P (on scope) in all positions of the mode switch without the Send switch flipped. When I flip the Send switch the voltage drops to .48V P-P. The CAR control has no affect on the signal level with the Send switch in either position.

I measure 8.97V at the CW terminal on CAR-2 when I flip the Send switch. I measure 8.94V at the anode of D1 and 8.19V at the cathode when the Send switch is flipped.

I have a couple of multimeters, a 150 MHz analog scope, 100 MHz digital scope, W7ZOI power meter, and a KA7EXM power meter. I feel comfortable taking measurements anywhere inside the radio including the Final Cage.

Ray AB7HE

For some reason I cannot read your entire response? It appears you are reporting back that you have good bias voltage available at the BM from the Car Pot. In CW TX mode you need this bias voltage and you need the local oscillator (LO) or Carrier to produce an output. Which in this case it is 8.830.70mhz CA-2 produced on the CAR-2 Unit.

You are getting CA-2 Carrier in FSK mode so it tells me the Crystal and the soldering at its pins have to be good.

If you have a RF millivolt meter or O-scope you can measure the 8830.7 mhz Carrier at the IF board at TP-5.TP-5 is tucked back in the corner under the chassis side rail. With rig in CW mode flip to send and measure the level and the frequency at TP-5. It should be approx 300mv rms or approx 850mv P-P on a scope at 8830.70mhz.

I would measure the level first before you look at it with a Freq Counter as the counter may pull the level down. If you dont have a means to measure CA-2 Carrier level and frequency then at minimum measure CW terminal at CAR-2 Unit board to make sure you are getting CW TX bias voltage.

If you remove the 2 screws that secure the cover you will see a white 10 pin connector. The 3rd pin from the Crystal is the CW terminal. When you flip to send in CW mode should see

approx 9.0vdc here. If you have 9vdc and still no output then suspect bad switching diode D1. D1 is close to the Crystal and you can measure the voltage at its anode and cathode. When you flip to send in CW mode should read approx 9vdc on the anode and approx 8.3vdc on the cathode. Note: The 9vdc will depend on where the AVR regulated 9vdc has been set too.

Ray

I forgot to mention where I am going with this (if not obvious) is a bad/dirty Mode switch contact or a broken wire at the mode switch in CW mode. The fact that you have output in FSK tells me that you do have approx 0.0 to 0.60vdc at TP-2 which then means the path from CV to the BM is good.

If you have no DMM, VOM, or VTVM the mode switch in a TS820 is an open deck type and pretty accessible with bottom cover off so you should be able to apply some deoxit and canned air to clean the contacts.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK well that would have been a quick fix and not first time so had to ask.

What test gear do you have and what is your comfort level to take measurements inside the rig?

When you inject audio into mic line and get output it tells you that your Balanced Modulator is working. In CW mode to produce output from the BM the Car Pot provides variable DC voltage to bias on the ring diodes. It is derives this bias voltage from regulated 9vdc from AVR board thru mode switch contacts.

The BM is on the IF board. Need to measure at Conn IF-5 at the CV terminal. Should see variable 0 to 9vdc at CV as you adjust the Car Pot thru its range.

Then measure at TP-2 and should see approx 0.0 to 0.70vdc as you adjust the Car Pot.

Ray:

Do you have a key in the key jack? If so remove it or key the key with Car Pot advanced. Cant load rig in CW mode if you have a key in key jack and it isnt closed. Brings back memories of the J-38 slider bar.

We can talk about plate dip not occurring at right place when we get CW working.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

Thanks for the comments.

1) I have 60 ma of current when I flip Send switch in CW, USB, and LSB modes. I don't have a microphone as I only operated CW back when I was on the air. I have a 1KHz tone generator and connected it to the microphone input. When I do this and increase MIC control in both USB and LSB I am able to drive plate current to the same 160 ma (on 20 meters) that I get in the FSK mode. So it appears CW is the only mode that isn't functioning.

2) I tuned the rig to the max power out (IP 160 ma) into the dummy load in the FSK position. I then switch to CW mode but the IP stays at 60 ma. This is with the CAR control at max (10 mark). Bias voltage drops from -100 to -63 volts when I flip Send switch in CW mode.

3) In the FSK mode I get almost FSD with CAR control at max on 20 meters in the ALC position. I am only 2 tick marks away from FSD. On 80, 40, and 160 I am able to get FSD at lower levels of the CAR control. However, when I turn SG back on and tune, the plate dip is in the wrong position for 40 and 160. For both of those bands max dip is at the very low end of 3.5 dial marking. On 20, 15, and 10 the dip is in the correct position. On 10 I am only able to get 80 ma of plate current at min dip with CAR at max. This does indicate the 12BY7 is bad. I think I have a spare one somewhere around here - just have to look. When I switch to USB or LSB I am able to get the same levels of ALC deflection as FSK when I inject the 1 KHz. However, in CW mode I do not get any ALC meter deflection.

4) I will perform this step once the rig is working.

5) I am using the dummy load because I have a 40 meter dipole 8 feet off the ground (HOA) as my only antenna and not sure of the impedance it reflects. I have a Heath HM-15 SWR bridge but it doesn't have a watts reading. I just received an order from Mouser yesterday with the parts to build the dummy load that is on the K4EAA website. I am including the power measurement components so I will be able to know what my power out is. Once I am back

on the air I will obtain an inline watt meter.

6) I haven't been on the air in 17 years and am wanting to get back on since I will be retiring in Jan and moving to somewhere that doesn't have a HOA. I have a HW-100 and a FT-101E that have sat in the garage for the last 17 years. I built the HW-100 back in 1968 and last used it in 1986. The FT-101 was working and I was using it on a daily basis when I went QRT at the end 1996. I bought this TS-820 10 years ago but have never used it. It has sat in the closet in my office since I bought it. I figured I would try to get it working first as it hasn't been exposed to extreme temperatures. I would be scared to power the other two up without replacing all the power supply caps first. My garage never drops below 100 four months out of the year.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

1. In LSB/USB should be 60ma resting plate current when you flip to send or key the mic. No indication on RF meter position until you modulate the rig (speak in mic). Can you see and adjust the resting plate current in SSB mode?

2. In Tune/CW will be plate current when you have RF drive (Car Pot advanced) only if you have RF drive as indicated by peaking the ALC indication with the Drive control.

Are you certain that Aux and TR relays are keying when you flip to send or key the mic? Sounds like they are based on seeing tube voltage dropping. Bias voltage at Finals control grid better not be dropping only 10%. It should change from approx -100vdc cutoff bias to approx -55vdc operating bias. If not then plate current and no RF output.

3. You can try a new 12BY7A as easy to do, but your rig has the diagnostic meter you need. Turn off SG switch and place rig in CW mode and peak the ALC indication by advancing the Car pot. Should be able to get full scale meter deflection (FSD) and hold there a few seconds on each band without the ALC indication falling off. Should get FSD with Car Pot advanced no more than approx 1000 to 1100. Rest between each band test as Driver tube is running class A (full plate current).

4 If RF detector is pegging at 70ma plate current then turn down the sensitivity pot. You always have to adjust the sensitivity pot. Set it for approx 2/3 deflection at 100 watts out. Would have been handy if KW would have put the pot on the front panel. They provided this meter position as it is better to load a Class AB1 linear amp by tuning for max rf output without exceeding plate dissipation than using the old dip and load method. They also provided it as external wattmeters were not common and they wanted the radio to be instrumented to be stand alone.

5. I would not use a 50 watt dummy load. If you must then have to realize all dummy loads have a duty cycle. Can use it but have to limit key down time.

6. When you get a couple of bucks ahead suggest you get an external wattmeter. Makes a good Loading aid and a good diagnostic tool. Drake W4, Heath HM-102, any of the MFJs are good and give you a SWR bridge and Wattmeter in one piece of test gear. Having actual output wattage tells you a lot more than looking at relative RF output power by measuring rf voltage at SO-239 or measuring the temperature of your dumm

Now that there is evidence of a HEATER switch failure which was not initially evident, you should take steps to replace the HEATER switch. Do not work on any other problems the radio has until the switch is replaced and found to be working as it should. That's my suggestion/steps you should take.

Very much aware, but my statement was very clear. 12 VAC feeds 2 tubes with 6 volt filaments in series, therefore 6VAC across each tube. Others also said the switch could be dirty. I am far from new with working on this type of gear. My wording was exactly what I have below in red. It was you who read it wrong thinking I thought 6VAC across 2 6 volt tubes etc., Not so. I stated A tube one 6146 would have the 6 volts on it; obviously the other would as well with 2 volts feeding it. I don't know how to write it any clearer. None the less, let's move on.

Ok yes, I certainly know that the threads can be numerous, but USUALLY if no one cuts anything off of previous posts, I see all of the thread and read it. Unfortunately this is a stickler with me that people have to cut off part of the thread. They say it's too long and they have to scroll through so much. Personally I believe it to be a issue with some and man do they make a big deal over it. I don't say anything when I have to sift through numerous posts to help someone out. It the thread is not cutoff and the replies are in order, the last one on that subject should be all I need. You also have to remember that others may respond at the same time or shortly before or after I do which I have no control over.

That's all. I agree with your frustration, but that is what we do and sometimes the same questions over and over. If you are going to help in a forum setting, one needs to just bite the bullet and repeat the same answers over and over.

I hope we understand each other on the situation of the filaments. Certainly this is a circuit I have in my head and I can easily explain it. I thought my response was perfectly clear. Yes, you nipped at me and it was your interpretation of what I wrote. Have a good day, Brad KB2CHY

Subject: Re: [TS-520_820_530_830] RE: Transmitter not working - No idling current, tubes not turning on.

Brad,

If you took my response as "biting you head off" then you took it wrong.

I am sorry Brad but I do not agree with the switch being intermittent. There is no evidence, at least at this stage, that indicates the switch is

intermittent. The presence of 12VAC at pin 2 of V1 final tube indicates the switch is not bad or even intermittent. An intermittent switch could easily show the filaments lit then dying out without touching the switch but that has not been indicated.

Your wording of your response about the filament voltage to the final tube indicated to me that you thought the final tube filament voltage should be 6.3VAC not 12VAC. I am aware the filament voltage for the 6146 is 6.3VAC but the 6146 filaments, as I said, in the 820 are wired in series so the filament voltage in the 820 will be 12VAC. Your indication of the 6146 filament wiring was not clear, you hinted that the final tubes were in series, which they are.

I don't mean any disrespect to anyone but it gets very frustrating and annoying when trying to help someone and they don't listen. They ask for help yet when given a few simple easy steps to take, they don't follow or if they do they do other things they are not told to do which quite often confuses the issue! That happens a lot on this and other ham forums and groups and it gets very frustrating and annoying!

Also, members need to read an entire thread before responding. It's quite possible that your response could duplicate a response given a few hours or half a day earlier.

On 10/23/2013 8:59 AM, Brad Allen wrote:

Mike, I said the switch could be bad because of the 140ma VAC reading. Obviously someone read something wrong. The filaments of the 6146's are in series with 12 volts which that means 6VAC at each filament. !2 volts AC would go to the 12BY7. So the12BY7 is in PARALLEL with 2 6146's in series and voltage across each supplied to the tubes. No, I did not read the whole thread. It seems that some don't want to get all the spaces and such on their portable devices, so some stuff is cutoff. I usually look at the last response. After I saw the 140ma VAC reading I was not sure what kind of know how you had, so I attempted the simple and easy route. I know what the schematic says without looking at it and I NEVER said the voltage to the tubes was 6 VAC. I said it was 12VAC so there should be 6 VAC across EACH tube in the final cage. The 12BY7 would be 12 volts. You asked for help in this, and I responded in good faith. No reason to be so quick to bite off my head. The switch could be intermittent or where the contacts can't handle the current. If you say the switch is not bad, OK, just say so. I am only trying to help you get you through a simple series parallel circuit.

Oh by the way, 2 6146's in SERIES with 12 volts applied would put 6 volts at each filament. That is a true statement. The driver is fed across the transformer with 12 volts. I will let you read what you wrote and analyze that again. I never said the TOTAL voltage across two 6146's is 6VAC, you did. I said ONE tube is 6VAC so the tubes may be in series which would equal the 12 VAC applied. Brad KB2CHY

. I believe the voltage to a 6146 should be 6.3 volts, not 12 volts. Please READ what I wrote. You will see I said to "A" 6146, not both.

NO the switch is NOT bad! Did you read the entire thread? It has already been determined that 12VAC IS present at pin 2 of final tube V1 (see below) so the switch can't be bad so why suggest it is!!!

"I checked filament voltage at pin 2 of V1, the 6146B. It's at 12VAC without the tubes inserted, as it should be."

You believe the 820 filament voltage to the 6146 filaments should be 6VAC? Why would you say that when the final tube filaments are wired in "series"? That would put "3VAC" across each final tube filament!! If you look at the 820 schematic you will clearly see that the final tube filaments are, in fact, wired in "series" AND the driver and both final tube filament voltage IS "12VAC" not "6VAC" as you thought!

Subject: [TS-520_820_530_830] RE: Transmitter not working - No idling current, tubes not turning on.

Some more information to the group. I checked filament voltage at pin 2 on V1, the 6146B. It's at 12 VAC without the tubes inserted, as it should be. However, with the tubes in, the voltage is at 140ma VAC. I would imagine it should stay at 12 VAC. I checked the HV, and the tubes are at 930 V when

power is on. The driver tube filaments are also not on when the HT switch is ON.

I checked the cathode resistors and they show 5 OHMS to ground.

I'm wondering why the filament voltage is dropping like that, is this normal?

---In TS-520_820_530_830@yahoogroups.com, <mailto:ts-520_820_530_830@yahoogroups.com> <ts-520_820_530_830@yahoogroups.com> wrote:

Hello, recently acquired a TS-820. The receive works great.

However, when attempting the Tuning procedure (Checking that all controls are set according to the manual), the ALC meter did not move at the first step. I checked the Idling current and it stays at zero. Removing the cover, I checked to see if the filaments on the 6164B's light up with the H. Switch on. They do not light up.

With HV set on the meter, I do read a little over 9 on the scale.

Where are some common places that would exhibit these symptoms in the transmitter portion of the radio so that I have a starting point on what to check. Do I check if the SG switch is functional, H. Switch? Ex ternal VFO cable is good. I checked that and all pins have continuity.

Any other starting bases begin troubleshooting?

Thank you!

This is BASIC electricity/electronics knowledge that ALL hams should know how to do. However, unfortunately many members don't believe they need to know this stuff so we end up with how this thread has gone!

Tackling one problem at a time is what should be done. Once the filament issue is solved I suspect the loss of 60ma idling current will no longer exist.

So, as you surmised in your *first* email, the heater switch is faulty. It's a bit of a bugger that you typoed 140mV AC as 140mA VAC because we've now had close to a week of people who ought to know better jumping up and down squawking about "ZOMG BASIC KNOWLEDGE!" when it was pretty clear from the outset that it was a) a typo, and b) a broken switch.

However, it's worth pointing out that this is the HEATER switch, and switches the heater supply. It's not the HT switch and it doesn't do a damn thing to the HT supply - that's still waiting there to bite the unwary! I don't think I've ever turned the heater switch off on my TS-520. Does anyone do this? I don't recommend wiring it across except as a temporary measure to test - but the amount of work to get at it to bodge it like that is as much as the amount of work to just replace the thing!

Now if we could just trim all the extraneous crap from replies and stop top-posting, this whole thing could have been cleared up a lot sooner ;-)

'know better jumping up and down squawking about "ZOMG BASIC KNOWLEDGE!"

Yeah this hobby and this forum would most assuredly be better if people like Mike Waldrop W5RKL would stop force feeding all this fundamental crap!

I submit this forum would be a better place if the owners would institute a more stringent membership approval screening process. Clearly needs to be a probationary period.

Let me see I have a technical problem with my KW hybrid. Who would I seek help from? Gordon or Mike ? Now there is a "No Brainer"!

Got to run now and go buy a bigger hammer.

With this severe drop in filament voltage. First I would check the tubes for a shorted heater to cathode. If the tubes are ok and you say without the tubes you have 12 vac then put the tubes back in and turn everything on and check each side of the heater switch to see what the voltage is there. If there is 12 vac on both sides of the switch, then you know it is ok. Also check pin 4 of the ext vfo socket for 12 vac. One other thing, do you have any meter and vfo lamps? These come from the same power source. You might want to check your power cord as well as pin 10 to pin 7 is jumper and if it has a bad solder joint or burned up pins you could lose the filament voltage. Also check pin 10 and pin 7 in the plug in the radio for bad solder joint or broken wires. Let me know what you find. my e-mail is in QRZ.

Oh "MM" I forgot to comment about who in their right mind would run with heater switch off.

I strongly counsel that all newly licensed hams who have purchased a KW hybrid as their first tube rig to do just that. It is simply good practice.

Until you have read the manual, familiarized yourself with the manual, learned how to load I would leave heater switch off. When you pull that Ebay purchase out of the box and anxious to plug it in and take a test drive make sure the Heater switch is off.

This is common sense. These people are very fortunate that KW provided this switch to facilitate mobile operation. If you have accidental or inadvertent transmit it can result in damage out of the box.

Take a look at every KW hybrid listed on Ebay over next month or two. Look at the pictures and note the power switch on, Heater on, flipped to Send, CAR pot advanced, meter in ALC. Doesnt it look grand with the meter lamps and VFO illuminated. Man I want to bid on that one. I wonder how long it has been keyed down and often keyed with no dummy load or antenna? I wonder how much plate current it sees during these picture taking sessions?

You can bid on these. I will pass.

Wake up man and put your thinking hat on. We are dealing with a very different knowledge and experience level here. The idea is to help these new people and cant do that if you assume a base knowledge that isnt there and worried about hurting someones feelings.

Use the Heater switch until you have gained a knowledge and experience level that will ensure no improper accidental transmit condition.

Ok, DeoxIT Cleaner solved the problem. The Heater switch was the culprit, causing these symptoms. Sprayed some Deoxit in there, toggled it a few times, let it rest a while, and now all correct voltages where they need to be. Filaments are lit, and I now get idling current. Probably other areas need some cleaning.

Thanks everyone, I learned quite a bit, even though it was the switch.

This is BASIC electricity/electronics knowledge that ALL hams should know how to do. However, unfortunately many members don't believe they need to know this stuff so we end up with how this thread has gone!

Tackling one problem at a time is what should be done. Once the filament issue is solved I suspect the loss of 60ma idling current will no longer exist.

The original questioner said â€œthe 820 filament voltage to the 6146 filaments should be 6VACâ€□. I suspect that what he meant was â€□the 820 filament voltage across each of the 6146 filaments should be 6Vacâ€□ which would be correct. I think itâ€™s a case of using an ambiguous form of words rather than a misapprehension that 6146 valves have a 3V filament.

Like everyone else, I am at loss to see where 140ma VAC comes from, even if 140ma, 140 mVAC or 140VAC was meant.

Guy â€“G3POM

On 10/23/2013 7:52 AM, Brad Allen wrote:

How can the voltage be 140ma VAC? Your issue is a simple one. No need to check high voltage or alignment of the radio. I believe the voltage to a 646 should be 6.3 volts, not 2 volts for one thing and I also believe that the two tubes may be in series. Try checking the RESISTANCE of the filaments of each tube. Do you have a schematic? You may want to trace right back to the transformer. You may have something as simple as a bad switch, quite common for those to go bad. Brad KB2CHY

Some more information to the group. I checked filament voltage at pin 2 on V1, the 6146B. It's at 12 VAC without the tubes inserted, as it should be. However, with the tubes in, the voltage is at 140ma VAC. I would imagine it should stay at 12 VAC. I checked the HV, and the tubes are at 930 V when power is on. The driver tube filaments are also not on when the HT switch is ON.
I checked the cathode resistors and they show 5 OHMS to ground.
I'm wondering why the filament voltage is dropping like that, is this normal?

Not sure what happened to my post yesterday afternoon, but I'll try again.

A "friend" of mine bought a 830 for a song, because it wouldn't transmit. He couldn't figure out why so I go involved with it. I d/l'd the schematic and did a little studying if it & then went to his QTH to look at it. After a few minutes of inspection I noticed that the solder on the tube socket Heater pins for the finals had sublimated or were never soldered very good. For some reason he could not see the issue. So I resoldered all 4 connections and VIOLA, it now had nice glowing heaters and full output. I told him I wanted to buy the unit when he was tired of it (he turned over units very quickly), but instead, he sold it to another have and made a big profit. So much for friendship. Resolder the heater pins just make sure they are electrically sound. It may not be obvious. – 73 Bob

From: Joe - W7RKN
Topic: 45439 Message: 45439

Gentle Readers.....

As an owner and/or moderator of several large Ham (And other non-ham) Groups, I see this 'complaint' more than a few times.

Just because you don't see your posts returned to you, rest assured, they are making it to the group. We are seeing every one you said didn't go out.

For some reason, Groups does not send your posts back to you, the sender. Some of my Groups do, others don't.

Joe Wolfe - W7RKN

Greetings Group!

Been gone of and on for a few days, and have been catching up on email.

For the "newer" people: yes, your messages are moderated until it shows that you can work and play well with others...usually not long.

The "moderators" live in different time zones and may not look at the message board after a certain time. Remember, I, we, they, are not paid and do this on a "volunteer"

basis.

I myself, being a co-owner of this group, have had emails take sometimes 24+ hours to show up. An now, with this new format, ...I'll stop there

Mike:

You hit the key word.....PASSION. It is like any other hobby or sport or business endeavor. If you dont have a passion for it you will never be very good. Certainly not among the best. I have a friend who lives and breathes Model A Fords and has a home shop where he does frame off restorations. He even taught himself how to pour and scrape the engine babbitt bearings. A lost art.

Having a passion versus an obsession is different of course. Better to have some balance in your life. At your age it is not too late to learn how to operate, maintain and repair the KW Hybrids. It wont be easy, but if you have an inquiring mind and the aptitude there are people here who will be willing to commit a lot of time to helping you.

Will require ability to read and read with comprehension and to follow instructions and to ask questions when you dont understand the directions. Will also require a modest amount of test equipment. Hard to play golf without clubs but doesnt have to be a set of Pings. Same with test gear dont need lab grade RF bench at this point.

If you just want to operate the Hybrid rigs and never take the covers off that is OK as well. Lots of help here regards accessories, how to tune/load etc.

I am glad you decided to join the KW hybrid ranks at this stage of your life.

Have fun.

Terry K9TW

>
> I strongly counsel that all newly licensed hams who have purchased a KW hybrid as their first tube rig to do just that. It is simply good practice.

That's a good point; I hadn't considered that people may buy these and have never tuned up a valve PA before.

> Take a look at every KW hybrid listed on Ebay over next month or two. Look at the pictures and note the power switch on, Heater on, flipped to Send, CAR pot advanced, meter in ALC. Doesnt it look grand with the meter lamps and VFO illuminated. Man I want to bid on that one. I wonder how long it has been keyed down and often keyed with no dummy load or antenna? I wonder how much plate current it sees during these picture taking sessions?

I hadn't noticed, but I have seen some sorry examples that people have picked up at rallies.

> Wake up man and put your thinking hat on. We are dealing with a very different knowledge and experience level here. The idea is to help these new people and cant do that if you assume a base knowledge that isnt there and worried about hurting someones feelings.

I wonder what the breakdown is of people who have bought these radios and never touched a hybrid before, compared to people who have used hybrid and all-valve radios for years? It's easy to forget that there are people out there who haven't grown up around KW2000s, FT101s and of course our beloved Trios.

Now that reminds me, I must track down whoever bought the KW2000 from my dad's silent key sale, and buy it back... ;-)

Hello to all,

I'm looking for help on my newly acquired TS-530. What a wonderful radio!

80 and 40 meters tunes like normal in transmit. When I tune on 20 meters and above, the plate tuning ends up with the indicator pointing just about straight down (deepest dip/max output).

Any help would be greatly appreciated.

Gary,

If your comfortable in removing the top cover with the radio turned off and allowed to discharge, have a look at the shaft and coupler and see if the screws are loose. These are usually locked with a loctite type of blue holding solution. But if the RF board has been taken out at some stage, the screws may not have been tightened enough or worked loose. As you say it is a new purchase and I'm unsure of your knowledge of tube radios. The dip can be very minor and with a new person unfamiliar with this type of tuning may not notice. Do you have a watt meter connected when tuning?

I'd suggest putting the load control dead centre of the band and start again looking for the minor dip, my preferred option is to have watt meter in-line. Try and then if no improvement report back and we can go from there, basic steps first and then we can go into more deeper and technical issues if need be.

Glad to hear your 820 is working fine now.

If I may make a suggestion, you might consider purchasing some jumper cables (see my video on Basic Test Equipment). These cables come in handy for problems such as this. A jumper cable used to jump around the HEATER switch should be capable of handling 3 amps. The filament current of a 6146B is 1.125 amps at 6.3VAC.

You could have used a single jumper cable to jump around the HEATER switch to see if the filaments light and/or 12.6VAC is present at the FINAL Unit's "H" terminal.

Hi Gary,
Into a good 50 ohm dummy load, mode TUNE, CAR set to give only a few Watts, rotate the PLATE cotrol and look for a dip around the 14 mark. It's possible to get two dips per 360 degrees rotation.

If I may add a comment or two to Dave's response.

Always set the LOAD control fully CCW (LOAD control knob pointing to 9 o'clock) when tuning the transmitter regardless of the band and always tune into a 50 ohm dummy load first. The 50 ohm dummy load should have a power rating of at least 200 watts or higher. If you don't have a 50 ohm dummy load I recommend you purchase or build one.

I'll bow out now and let Dave continue helping you with this problem.

I mistyped the test equipment video file name. The video file name is "Test Equipment". I'm doing some changes so not all video files are available. They all should be available shortly, at mid day tomorrow at the latest.

Hi Mike,

Thanks for the quick supply and suggestions.

I always set the load control to the 9:00 position when I change bands and re-tune. And, I always tune into an old Heathkit Cantenna!

gary ai4ja

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

If I may add a comment or two to Dave's response.

Always set the LOAD control fully CCW (LOAD control knob pointing to 9 o'clock) when tuning the transmitter regardless of the band and always tune into a 50 ohm dummy load first. The 50 ohm dummy load should have a power rating of at least 200 watts or higher. If you don't have a 50 ohm dummy load I recommend you purchase or build one.

I'll bow out now and let Dave continue helping you with this problem.

Gary,

If your comfortable in removing the top cover with the radio turned off and allowed to discharge, have a look at the shaft and coupler and see if the screws are loose. These are usually locked with a loctite type of blue holding solution. But if the RF board has been taken out at some stage, the screws may not have been tightened enough or worked loose. As you say it is a new purchase and I'm unsure of your knowledge of tube radios. The dip can be very minor and with a new person unfamiliar with this type of tuning may not notice. Do you have a watt meter connected when tuning?

I'd suggest putting the load control dead centre of the band and start again looking for the minor dip, my preferred option is to have watt meter in-line. Try and then if no improvement report back and we can go from there, basic steps first and then we can go into more deeper and technical issues if need be.

Subject: [TS-520_820_530_830] TS-530 TX Tune

Hello to all,

I'm looking for help on my newly acquired TS-530. What a wonderful radio!

80 and 40 meters tunes like normal in transmit. When I tune on 20 meters and above, the plate tuning ends up with the indicator pointing just about straight down (deepest dip/max output).

Any help would be greatly appreciated.

Hi Dave,

Thanks for the quick reply.

This radio is an upgrade from my TS-520S so I'm familiar with tube radios.

Earlier, I removed the covers and checked the shaft coupler screws and shaft alignment. All were in good order. I also cleaned the band switches.

Hi Dave,

Thanks for the quick reply and suggestion.

This was very interesting. I think you meant 180 degrees rotation.

I tried this and I didn't get any dip around the 14 mark.

I said the switch could be intermittent and was told straight out that the switch could not be intermittent or bad because there was voltage on the tubes. I also noticed the batteries were going down on my keyboard and the digit 1 did not take when I hit it, so my post said 2 volts instead of 12. Take a look; you will see the pattern show up. Yes I felt beat up over the rejection of my response, but that’s ok because I know what I said even though it was not read as I meant to write it. (Haha) Figure that one out. Brad KB2CHY

Ok, DeoxIT Cleaner solved the problem. The Heater switch was the culprit, causing these symptoms. Sprayed some Deoxit in there, toggled it a few times, let it rest a while, and now all correct voltages where they need to be. Filaments are lit, and I now get idling current. Probably other areas need some cleaning.

Thanks everyone, I learned quite a bit, even though it was the switch.

This is BASIC electricity/electronics knowledge that ALL hams should know how to do. However, unfortunately many members don't believe they need to know this stuff so we end up with how this thread has gone!

Tackling one problem at a time is what should be done. Once the filament issue is solved I suspect the loss of 60ma idling current will no longer exist.

The original questioner said â€œthe 820 filament voltage to the 6146 filaments should be 6VACâ€□. I suspect that what he meant was â€□the 820 filament voltage across each of the 6146 filaments should be 6Vacâ€□ which would be correct. I think itâ€™s a case of using an ambiguous form of words rather than a misapprehension that 6146 valves have a 3V filament.

Like everyone else, I am at loss to see where 140ma VAC comes from, even if 140ma, 140 mVAC or 140VAC was meant.

Guy â€“G3POM

On 10/23/2013 7:52 AM, Brad Allen wrote:

How can the voltage be 140ma VAC? Your issue is a simple one. No need to check high voltage or alignment of the radio. I believe the voltage to a 646 should be 6.3 volts, not 2 volts for one thing and I also believe that the two tubes may be in series. Try checking the RESISTANCE of the filaments of each tube. Do you have a schematic? You may want to trace right back to the transformer. You may have something as simple as a bad switch, quite common for those to go bad. Brad KB2CHY

Some more information to the group. I checked filament voltage at pin 2 on V1, the 6146B. It's at 12 VAC without the tubes inserted, as it should be. However, with the tubes in, the voltage is at 140ma VAC. I would imagine it should stay at 12 VAC. I checked the HV, and the tubes are at 930 V when power is on. The driver tube filaments are also not on when the HT switch is ON.

I checked the cathode resistors and they show 5 OHMS to ground.

I'm wondering why the filament voltage is dropping like that, is this normal?

---In TS-520_820_530_830@yahoogroups.com , mailto:ts-520_820_530_830@yahoogroups.com wrote:

Hello, recently acquired a TS-820. The receive works great.

However, when attempting the Tuning procedure (Checking that all controls are set according to the manual), the ALC meter did not move at the first step. I checked the Idling current and it stays at zero. Removing the cover, I checked to see if the filaments on the 6164B's light up with the H. Switch on. They do not light up.

With HV set on the meter, I do read a little over 9 on the scale.

Where are some common places that would exhibit these symptoms in the transmitter portion of the radio so that I have a starting point on what to check. Do I check if the SG switch is functional, H. Switch? Ex ternal VFO cable is good. I checked that and all pins have continuity.

Any other starting bases begin troubleshooting?

Thank you!

Terry,

Are the transmit levels on page 42 of the service manual correct? Are those RMS values?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Thanks Terry. I have been talking to you since you have been helping. I don't know what made me put Dave on the last message (old age maybe).

I decided to start over from the beginning and go stage by stage this afternoon. This is what I did:
(All measurements taken with Send switch operated and Mode switch in CW position. Also, the measurements are the same in both CW and FSK modes.)

I suspected D1 or L1 was bad on the CAR-II board was bad but that is not the case. I have 720mV on CA2 leaving the CAR-II board in both CW and FSK send modes. I also have 720mV P-P on CA2 (IF5-13) on the IF board. I have 100mV P-P at the coax that connects to C92 on the IF board. On the other end of that coax where it connects to the top of T4 on the IF board I also have 100mV P-P. I would have thought the signal out of Q18 would have been stronger but maybe not.

I have 340mV at the junction of the cathode of D7 and C14 on the IF board. I have 280mV on the side of C14 where it feeds the CW filter. The signal going into the filter measures 8.830755 MHz. I only have 6mV P-P coming out of the crystal filter. Is the crystal filter used for transmit?

I connected the antenna to the radio and 20 meters is open. Tuning in CW signals in USB mode and switching to CW mode drops the signal by about 1 S-Unit when the signal is peaked for max signal in both modes.

Where do I go from here?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Are you talking Dave or Terry ? If someone is helping you off list I can back away as I have a pretty full plate right now.

I am not clear where you are measuring this 40mv P-P signal at?

Before I go I will mention that it is normal to not have a clean sine wave at TIF. It does have harmonic content and it is as you say due to LO mixing action. In this case it is coming from the VCO signal feeding back from the TX Mixer on RF board to the IF board.

This is easy to confirm with a TS-830 as you can easily unplug the VCO cable from the PLL board and the TIF signal will then be a nice clean 8.830mhz sine wave.

Dont worry about the complex waveform. Should still be able to get a reasonably close TIF measurement. It may not match exactly the levels on the TX Level Diagram,but you can compare it to the level you get with FSK carrier oscillator.

I dont use a O-scope to run TX Level diagrams once I get to the output of the TIF amp. I use a Boonton RF Millivolt meter and measure levels in rms and the "dirty" TIF signal presents no problem.

I have a new digital O-scope and it has a variety of digital filters. If I set it for a LP filter with a roll off frequency of 10mhz I can get a pretty clean 8.830 TIF sine wave display.

I dont know the Tek 2445 capability in this regard.

One final reminder is that good TIF signal level of approx 38mv rms or 107mv P-P is based on the premise that you accurately measured CA2 at the iF board of approx 300mv rms or 850mv P-P.

If that signal is not there then you would need to repeat the testing I asked you to do at the Carrier Osc board to confirm the 9vdc CW diode switching voltage is available at D1 and Q2 Buffer amp is being turned on.

I have been providing direction based on your reporting back that you have good CA-2 at Carrier board and good CA-2 at TP-5 on IF board.

If good Level at TP-5 then should have proper level at the wiper of VR-5 on the Balanced Mod. As we have discussed. No dc bias from CV and no Carrier at wiper of VR-5 then no output from the Bal Modulator.

I am pretty confident that you do have proper bias voltage from CCW to full CW on the Car Pot, but I am not certain yet that you have proper carrier output from the BM in CW mode.

Good luck.

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Dave,

I have VFO set to 14.175. With Car pot at 1200, in CW mode I get 40mV P-P in RX mode. When I flip the Send switch, the signal stays at 40 mV but it is no longer a sine wave. It is some kind of more or less sine wave with a lot of noise on it. With the Car pot at max, the noisy sinewave increases to 60 mV P-P in Send mode.

In FSK mode with Car at 1200 I get 250mV P-P in Send mode. With Car at Max I get 800 mV P-P in Send mode.

At Conn RF1-10 I get 140mV P-P in CW Send mode. I get 800mV P-P in FSK Send mode.

At the mixer output (Q1 and Q8 side of C8) I get 100 mV P-P in CW Send mode. I get 1V P-P in FSK Send mode. The signal at that point is not a sinewave but seems to have multiple signals. Probably some LO feedthrough on the mixer. The frequency counter agrees with the Kendwood readout as 14.1748 MHz.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Sorry about Q10 vs Q18. My fingers work better than what is left of my brain.

The 3 conductor plug should be positioned in forward position toward the front panel.

One thing we did not talk about is whereiyou should have the Car Level Pot set to take these measurements.

The TX Level Diagram is shown in the Service Manual. These levels were taken by Kenwood by loading the rig to approx 100 watts out at 14.175mhz and then turn the SG switch off and leave Car pot alone and Drive control alone.

Since you have no RF output in CW mode I suggest you do this for remainder of the readings:

1. VFO 14.175
2. Peak the Drive Control on receiver noise or the marker signal
3. Car Level Pot 1200
4. Heater on
5. SG switch off
6. Flip to Send to take RF drive levels

So the differences in voltages may be due to where we each have our Car Level pot set at.

Suggest you measure the voltage and frequency of the TIF signal at IF-3 Pin 2 one more time and it should be approx 250mv rms or 700mv P-P @ 8830.7mhz.

If you have close to this time to move on to the RF board. I must say this is getting a little odd as you have good output ini SSB and FSK which tells us you have good TIF level and the TX Mixer on RF Board is working which means you have good VCO (LO to the mixer).

Are you 100% certain you have no CW RF output on all bands? If so, then proceed on to the RF board with Heaters On and SG off and rig peaked as noted above.

You should have close to the values noted on the TX Level Diagram. At Conn RF-1 Pin 10 the 8.830 TIF signal level is approx 38mv rms or 108 P-P.

At output of TX Mixer should have approx 1.5v rms or 4.2v P-P rf drive at MD. At MD frequency will now be 14.175mhz transmit frequency.

If you have no RF drive or very weak at MD then need to measure the VCO level and frequency at RF-1 pin 4 and on board at TP-1. Should be close to 1.0v rms level. If no VCO try on other bands.

We are making good progress. Your Tek 2445 is perfect scope for KW Hybrid work and you apparently know how to use it and can read a schematic and can locate points on these high density boards to take measurements. This really helps.

Based on your report of no RF output in CW mode I would have thought we would have found no TIF sig at output of the IF board. TIF is not band specific and often is caused by no output from the Bal Modulator, This is why I had you start by testing for bias voltage and LO signal available. Never expected that we would be at the RF board and TX Mixer based on good RF output on other modes.

Terry,

I read a little over 700mV at the drain of Q18 (actually the backside of C92 feeding the coax). I think you meant Q18 instead of Q10.

D7 and D8 are the CW switching diodes. With the mode switch in CW position, I have 2.98 volts on the anode of D7 and 2.34 volts on the cathode. I have 10.0 volts on the anode of D8 and 9.40 volts on the cathode. These voltages are there in both RX and TX, just a few 10ths of a volt lower in TX mode.

Can you confirm how the 3 pin cable ofr IF2 is supposed to plug in? It only has 3 wires but there are 5 pins on the IF board at that point. According to the chassis wiring diagram, only the first 3 pins are used as they come from S6-1.

I don't think there is anything wrong with the CW filter and the switching diodes as the CW filter works fine in RX mode.

I have 400mV P-P on Gate 1 of Q1 instead of the 160mV when flipping Send. I also have 2400mV P-P on the drain instead of 1000mV when flipping Send.

TIF signal on Conn IF-3 is 400mV P-P and the sine wave isn't quiet as clean there as it is on the drain of Q1.

Hopefully we are making progress.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Good job. Much better.

If I understand your chart you are telling me that you have approx 640mv P-P @ 8.83077 at TP-5 in CW mode with rig flipped to Send (heaters off and SG switch off). 900mv P-P is attainable by adjusting T1 on CAR-2 board, but can do later unless you want to peak it now. 640mv will work for testing.

If this is true then you have confirmed that you have the two things you need at the Balanced Mod to produce RF output from it in CW mode. 1. Offset bias voltage and 2. Proper Carrier freq and level.

From the BM output the CW signal is routed to the Crystal IF Filter and then to Q1 the Transmit IF Amp or TIF amp. TIF signal leaves the IF board and is routed to the RF board to the TX Mixer where it is mixed with VCO to produce the actual transmit rf drive signal. No TIF signal and there will be no RF drive and no RF output. Also no VCO or low VCO level and no rf drive. Lets validate that we have TIF signal in CW mode first.

Unfortunately KW didnt provide a nice test point at the output of the Balanced Mod to measure the DSBSC signal in SSB mode or the Carrier in CW mode. However, you can get on the Drain of Q10 with a hat pin or floral arrangement pin and mini-grabber test lead. If you

locate the BM ring diodes D26-D29 and then output Xfmr T10 you will see Q10. It is a metal can dual gate mosfet. Looking down on the can the Drain is the upper right lead. You should read approx 800mv P-P here. This signal is routed to the Xtal filter thru switcing diodes.

Do you have the CW filter installed. It is rare but could have a bad filter. More common to have a bad switching diode.

After signal passes thru the Xtal filter it is applied to Gate 1 of TIF amp Q1. It is also a metal can dual gate mosfet and sits outside and almost between the two filters at the inboard end. Looking down on Q1 Gate 1 is at 1200. Should have approx 160mv P-P here. The Drain is at 0600 and should have approx 1000mv P-P. TIF output is on Conn IF-3 Pin 2 and should have approx 850mv P-P here. You can jump right to measuring TIF output if you want and if good then off to the RF board.

We know that you have TIF output in FSK mode as you reported good RF output in that mode. I dont kow if you keyed rig in FSK and noted the 170hz shift or not, but not important right now. Also, you should have noted that the RF output in FSK is lower as the 820 lowers the Finals Screen Grid voltage in FSK mode so the tubes plate dissipation is not exceeded in this high duty cycle mode.

That should be enough for now.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

This is what I am seeing:
TP-5 and CJ3-CA2 have the same levels in CW and FSK modes: 820mV P-P in RX mode. Flipping Send switch the level drops to 640mV P-P. I have a Tektronix 2445 Scope and have the probe in 10X to prevent loading the circuit.

Frequencies measured at CJ3-CA2:
RX mode FSK - 8.828414 - TX mode FSK 8.830620
RX mode LSB - 8.828414 - TX mode LSB 8.828579
RX mode USB - 8.831460 - TX mode USB 8.831625
RX mode CW - 8.831460 - TX mode CW 8.830777

Frequencies measured at TP-5:
RX mode FSK - 8.828410 - TX mode FSK 8.830616
RX mode LSB - 8.828410 - TX mode LSB 8.828575
RX mode USB - 8.831450 - TX mode USB 8.831622
RX mode CW - 8.831446 - TX mode CW 8.830773

I am using a Simpson 710 Frequency counter. Specs say 1 Meg input shunted by 30 pF. The slight differences in frequency readings between CJ3-CA2 and TP-5 is probably due to the cable capacitance of the cable between IF5-13 and CJ3-CA2.

I have been taking all of these measurements with the SG switch turned off and the heater switch turned off.

Ray:

I mis-spoke in Item 2 when I said you cant measure carrier at TP-5 in Rx in any of the mode switch positions. There will be legitimate carrier but not of interest.

There will be Carrier at CA-2 and TP-5 in Rx in all positions of the mode switch that you should see, but it is meaningless for CW Tx operation. It was not correct for me to label it as "Leakage" signals.

It is there by design but not for Rx or Tx operation. CA-1 Carrier Osc signals are coupled to the CAR-2 board to amp Q3 and then on to TP-5 at IF board and then sampled and sent to the CCR lead to provide carrier oscillator signals for the Counter Mixer Board. So the carrier osc signals you were measuring at each position of the mode switch in Rx are there by design to feed the counter, but of no interest to us as not utilized for the BM and CW transmit.

So you will see approx 250mv rms at 8831.50 mhz in CW and LSB and 250mv at 8828.5mhz in LSB and FSK, but not used by the BM. BM is not used in Rx operation. So disregard these signal other than the low levels you measured cannot be correct if your counter is working properly. I suspect you are not using O-scope properly. Are you using a 10X probe?

What I meant to say is at CA-2 and TP-5 the only frequency and level we care about is in CW and FSK positions of the mode switch in Tx. CA-2 carrier oscillator should be approx 250mv rms @ 8830.70mhz when in CW and FSK mode when flipped to send. This is what you are trying to validate. Measure at TP-5 in FSK as you know it is working. So use it to get your O-scope set up correctly and you can see approx 850mv P-P at 8830.7mhz. Once you can read that on your O-scope now switch to CW mode and flip to send to measure carrier osc signal level at TP-5.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Yes this new format gives me problems as well.

1. You are getting proper dc bias voltage to the BM. You need to confirm you are getting the Carrier Osc signal.

2. You cannot measure any Carrier freq or level at TP-5 in RX for any position of the mode switch. You may read some leakage signals in RX mode but meaningless. The BM is only used for TX and not RX. Only time you can measure any meaningful Carrier Osc frequency or level at TP-5 is in TX with the mode switch in CW or FSK. Carrier in RX mode is applied to another Mixer called the Product Detector and it arrives at IF board on IF-4 C1A terminal. You have separate Carrier Oscillators for RX and TX.

Also, the Car Level Pot has nothing to do with the Carrier Osc levels produced on the CAR Assembly Unit. The Car level pot unbalances the balanced modulator and determines the carrier output level from the BM.

You really need to measure CA-2 produced on the CAR-2 board. If you do not have 300mv of 8830.7mhz at TP-5 in CW mode when you flip to Send then you have to work your way back from TP-5 to CAR-2 board. CA2 can be checked on the 7th terminal up on the white terminal block on the CAR-2 board. On the IF board it comes in on Conn IF-5 pin 13.

At this point you have not confirmed that you have CAR-2 Q1 Oscillator running and available.

3. The DC voltages that you measured at D1 prove that you are getting the turn on voltages for Buffer amp Q2 so if Q1 is oscillating should get CW TX Carrier at CJ-3 and on to the IF board if all connectors are good.

You may have to adjust the frequency and output level but can talk about that later.

Suggest you buy a Freq Counter. Can measure Freq roughly with O-scope. Some measure and display Freq (may or may not do so accurately) and some require using F=1/T and not accurate enough for adjusting the Oscillators in the KW hybrids.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Let's try this again. For some reason yahoo has been mangling my posts. This has been a problem ever since they went to this new stupid format they are using.

Measuring at TP-2 the voltage varies from 16 mV to .443V when adjusting the CAR control in both FSK and CW mode. On Conn IF-5 at the CV terminal, the voltage varies from .12V to 8.95V in both FSK and CW mode when adjusting the CAR control.

Also, on the FIX VOX board FIX3-11 is grounded with no key plugged in. Plugging a key in, FIX3-11 follows the key (open key up, grounded key down).

I have cleaned the contacts on the Mode switch and checked for broken wires.

At TP-5 I measure 8.831434 MHz at .64V P-P (on scope) in all positions of the mode switch without the Send switch flipped. When I flip the Send switch the voltage drops to .48V P-P. The CAR control has no affect on the signal level with the Send switch in either position.

I measure 8.97V at the CW terminal on CAR-2 when I flip the Send switch. I measure 8.94V at the anode of D1 and 8.19V at the cathode when the Send switch is flipped.

I have a couple of multimeters, a 150 MHz analog scope, 100 MHz digital scope, W7ZOI power meter, and a KA7EXM power meter. I feel comfortable taking measurements anywhere inside the radio including the Final Cage.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

For some reason I cannot read your entire response? It appears you are reporting back that you have good bias voltage available at the BM from the Car Pot. In CW TX mode you need this bias voltage and you need the local oscillator (LO) or Carrier to produce an output. Which in this case it is 8.830.70mhz CA-2 produced on the CAR-2 Unit.

You are getting CA-2 Carrier in FSK mode so it tells me the Crystal and the soldering at its pins have to be good.

If you have a RF millivolt meter or O-scope you can measure the 8830.7 mhz Carrier at the IF board at TP-5.TP-5 is tucked back in the corner under the chassis side rail. With rig in CW mode flip to send and measure the level and the frequency at TP-5. It should be approx 300mv rms or approx 850mv P-P on a scope at 8830.70mhz.

I would measure the level first before you look at it with a Freq Counter as the counter may pull the level down. If you dont have a means to measure CA-2 Carrier level and frequency then at minimum measure CW terminal at CAR-2 Unit board to make sure you are getting CW TX bias voltage.

If you remove the 2 screws that secure the cover you will see a white 10 pin connector. The 3rd pin from the Crystal is the CW terminal. When you flip to send in CW mode should see approx 9.0vdc here. If you have 9vdc and still no output then suspect bad switching diode D1. D1 is close to the Crystal and you can measure the voltage at its anode and cathode. When you flip to send in CW mode should read approx 9vdc on the anode and approx 8.3vdc on the cathode. Note: The 9vdc will depend on where the AVR regulated 9vdc has been set too.

Ray

I forgot to mention where I am going with this (if not obvious) is a bad/dirty Mode switch contact or a broken wire at the mode switch in CW mode. The fact that you have output in FSK tells me that you do have approx 0.0 to 0.60vdc at TP-2 which then means the path from CV to the BM is good.

If you have no DMM, VOM, or VTVM the mode switch in a TS820 is an open deck type and pretty accessible with bottom cover off so you should be able to apply some deoxit and canned air to clean the contacts.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK well that would have been a quick fix and not first time so had to ask.

What test gear do you have and what is your comfort level to take measurements inside the rig?

When you inject audio into mic line and get output it tells you that your Balanced Modulator is working. In CW mode to produce output from the BM the Car Pot provides variable DC voltage to bias on the ring diodes. It is derives this bias voltage from

regulated 9vdc from AVR board thru mode switch contacts.

The BM is on the IF board. Need to measure at Conn IF-5 at the CV terminal. Should see variable 0 to 9vdc at CV as you adjust the Car Pot thru its range.

Then measure at TP-2 and should see approx 0.0 to 0.70vdc as you adjust the Car Pot.

Ray:

Do you have a key in the key jack? If so remove it or key the key with Car Pot advanced. Cant load rig in CW mode if you have a key in key jack and it isnt closed. Brings back memories of the J-38 slider bar.

We can talk about plate dip not occurring at right place when we get CW working.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

Thanks for the comments.

1) I have 60 ma of current when I flip Send switch in CW, USB, and LSB modes. I don't have a microphone as I only operated CW back when I was on the air. I have a 1KHz tone generator and connected it to the microphone input. When I do this and increase MIC control in both USB and LSB I am able to drive plate current to the same 160 ma (on 20 meters) that I get in the FSK mode. So it appears CW is the only mode that isn't functioning.

2) I tuned the rig to the max power out (IP 160 ma) into the dummy load in the FSK position. I then switch to CW mode but the IP stays at 60 ma. This is with the CAR control at max (10 mark). Bias voltage drops from -100 to -63 volts when I flip Send switch in CW mode.

3) In the FSK mode I get almost FSD with CAR control at max on 20 meters in the ALC position. I am only 2 tick marks away from FSD. On 80, 40, and 160 I am able to get FSD at lower levels of the CAR control. However, when I turn SG back on and tune, the plate dip is in the wrong position for 40 and 160. For both of those bands max dip is at the very low end of 3.5 dial marking. On 20, 15, and 10 the dip is in the correct position. On 10 I am only able to get 80 ma of plate current at min dip with CAR at max. This does indicate the 12BY7 is bad. I think I have a spare one somewhere around here - just have to look. When I switch to USB or LSB I am able to get the same levels of ALC deflection as FSK when I inject the 1 KHz. However, in CW mode I do not get any ALC meter deflection.

4) I will perform this step once the rig is working.

5) I am using the dummy load because I have a 40 meter dipole 8 feet off the ground (HOA) as my only antenna and not sure of the impedance it reflects. I have a Heath HM-15 SWR bridge but it doesn't have a watts reading. I just received an order from Mouser yesterday with the parts to build the dummy load that is on the K4EAA website. I am including the power measurement components so I will be able to know what my power out is. Once I am back on the air I will obtain an inline watt meter.

6) I haven't been on the air in 17 years and am wanting to get back on since I will be retiring in Jan and moving to somewhere that doesn't have a HOA. I have a HW-100 and a FT-101E that have sat in the garage for the last 17 years. I built the HW-100 back in 1968 and last used it in 1986. The FT-101 was working and I was using it on a daily basis when I went QRT at the end 1996. I bought this TS-820 10 years ago but have never used it. It has sat in the closet in my office since I bought it. I figured I would try to get it working first as it hasn't been exposed to extreme temperatures. I would be scared to power the other two up without replacing all the power supply caps first. My garage never drops below 100 four months out of the year.

45459. TS-520S screen voltage rectifier board & schematic

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-25 05:59:48 UTC
From: <lonelyone_64109@...>
Topic: 45459 Message: 45459

I am working on a TS-520S that has its screen grid and cathode resistors burned up. After replacing the resistors I am tracing the screen grid supply back to the rectifier board and found R5 open. Someone who owned the rig many years ago had put a 10 ohm resistor across R5 which probably caused the demise of not only the resistors but has probably caused the final to get "cooked". Evidently whoever owned the rig years ago had a final tube go out and instead of putting the right value resistor in they stuck a 10 ohm resistor in instead.

In studying the schematic in both the owner's and service manuals I found there were 2 R5 resistors, Both are 470 ohm and one is in series with D5 whereas the other R5 goes from the output of the rectifier board (300V) to ground. Is this a misprint?

Is there an easy way of tilting the rectifier board so I can replace the now open R5? Short of disconnecting the wires from the board and taking it out I don't see any way to tilting the board which leads to the fact I will probably have to solder a new 470 ohm resistor across the old one in order to complete the circuit. Once that is done I can proceed with checking the plate choke, doing resistance and the voltage checks with the finals not installed. Once I am satisfied with the readings only then will a new pair of tubes be plugged in.

From: <wagstw46@...>
Topic: 45375 Message: 45461

Yes they are RMS.

I take them at around 14.175 to 14.200 mhz with the Car Level pot advanced to the point that with the Drive Control adjusted for a peak in ALC indication at panel meter full scale deflection. Then switch to CW mode and load to approx 100 watts out and turn off SG switch. Leave Car Level and Drive control alone.

Measured values will vary depending on what test instrument you are using, length of any test jumper leads used to access the test points, line voltage.

For example 8.830mhz TIF output at the IF board and input at the RF board is shown as 0.038v. This is 38.0 mv rms rf volts or 38 x 2.828 = 107 mv P-P. So if you have approx 100mv P-P TIF you are good.

Output of the TX Mixer is 1.4v rms or 4.0v P-P. This RF drive level is now 14.175 mhz.

If you plan on doing a lot of this work suggest you invest in a RF Millivolt meter. I use a Boonton 92E. I find it loads the circuits less and just easier and faster to use.

Of coures once you get to the 1.4 volts at output of the TX Mixer the old fashioned RF probe and VTVM works great. Just have to use multi-diode probe at plate of Driver tube and control grids of the Finals. I used a Heath 309C and PK-3 probes and a IM-18 VTVM for years and still have them for fall back.

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Thanks Terry. I have been talking to you since you have been helping. I don't know what made me put Dave on the last message (old age maybe).

I decided to start over from the beginning and go stage by stage this afternoon. This is what I did:
(All measurements taken with Send switch operated and Mode switch in CW position. Also, the measurements are the same in both CW and FSK modes.)

I suspected D1 or L1 was bad on the CAR-II board was bad but that is not the case. I have 720mV on CA2 leaving the CAR-II board in both CW and FSK send modes. I also have 720mV P-P on CA2 (IF5-13) on the IF board. I have 100mV P-P at the coax that connects to C92 on the IF board. On the other end of that coax where it connects to the top of T4 on the IF board I also have 100mV P-P. I would have thought the signal out of Q18 would have been stronger

but maybe not.

I have 340mV at the junction of the cathode of D7 and C14 on the IF board. I have 280mV on the side of C14 where it feeds the CW filter. The signal going into the filter measures 8.830755 MHz. I only have 6mV P-P coming out of the crystal filter. Is the crystal filter used for transmit?

I connected the antenna to the radio and 20 meters is open. Tuning in CW signals in USB mode and switching to CW mode drops the signal by about 1 S-Unit when the signal is peaked for max signal in both modes.

Where do I go from here?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Are you talking Dave or Terry ? If someone is helping you off list I can back away as I have a pretty full plate right now.

I am not clear where you are measuring this 40mv P-P signal at?

Before I go I will mention that it is normal to not have a clean sine wave at TIF. It does have harmonic content and it is as you say due to LO mixing action. In this case it is coming from the VCO signal feeding back from the TX Mixer on RF board to the IF board.

This is easy to confirm with a TS-830 as you can easily unplug the VCO cable from the PLL board and the TIF signal will then be a nice clean 8.830mhz sine wave.

Dont worry about the complex waveform. Should still be able to get a reasonably close TIF measurement. It may not match exactly the levels on the TX Level Diagram,but you can compare it to the level you get with FSK carrier oscillator.

I dont use a O-scope to run TX Level diagrams once I get to the output of the TIF amp. I use a Boonton RF Millivolt meter and measure levels in rms and the "dirty" TIF signal presents no problem.

I have a new digital O-scope and it has a variety of digital filters. If I set it for a LP filter with a roll off frequency of 10mhz I can get a pretty clean 8.830 TIF sine wave display.

I dont know the Tek 2445 capability in this regard.

One final reminder is that good TIF signal level of approx 38mv rms or 107mv P-P is based on the premise that you accurately measured CA2 at the iF board of approx 300mv rms or 850mv P-P.

If that signal is not there then you would need to repeat the testing I asked you to do at the Carrier Osc board to confirm the 9vdc CW diode switching voltage is available at D1 and Q2 Buffer amp is being turned on.

I have been providing direction based on your reporting back that you have good CA-2 at Carrier board and good CA-2 at TP-5 on IF board.

If good Level at TP-5 then should have proper level at the wiper of VR-5 on the Balanced Mod. As we have discussed. No dc bias from CV and no Carrier at wiper of VR-5 then no output from the Bal Modulator.

I am pretty confident that you do have proper bias voltage from CCW to full CW on the Car Pot, but I am not certain yet that you have proper carrier output from the BM in CW mode.

Good luck.

Terry K9TW.

Dave,

I have VFO set to 14.175. With Car pot at 1200, in CW mode I get 40mV P-P in RX mode. When I flip the Send switch, the signal stays at 40 mV but it is no longer a sine wave. It is some kind of more or less sine wave with a lot of noise on it. With the Car pot at max, the noisy sinewave increases to 60 mV P-P in Send mode.

In FSK mode with Car at 1200 I get 250mV P-P in Send mode. With Car at Max I get 800 mV P-P in Send mode.

At Conn RF1-10 I get 140mV P-P in CW Send mode. I get 800mV P-P in FSK Send mode.

At the mixer output (Q1 and Q8 side of C8) I get 100 mV P-P in CW Send mode. I get 1V P-P in FSK Send mode. The signal at that point is not a sinewave but seems to have multiple signals. Probably some LO feedthrough on the mixer. The frequency counter agrees with the Kendwood readout as 14.1748 MHz.

Ray:

Sorry about Q10 vs Q18. My fingers work better than what is left of my brain.

The 3 conductor plug should be positioned in forward position toward the front panel.

One thing we did not talk about is whereiyou should have the Car Level Pot set to take these measurements.

The TX Level Diagram is shown in the Service Manual. These levels were taken by Kenwood by loading the rig to approx 100 watts out at 14.175mhz and then turn the SG switch off and leave Car pot alone and Drive control alone.

Since you have no RF output in CW mode I suggest you do this for remainder of the readings:

1. VFO 14.175
2. Peak the Drive Control on receiver noise or the marker signal
3. Car Level Pot 1200
4. Heater on
5. SG switch off
6. Flip to Send to take RF drive levels

So the differences in voltages may be due to where we each have our Car Level pot set at.

Suggest you measure the voltage and frequency of the TIF signal at IF-3 Pin 2 one more time and it should be approx 250mv rms or 700mv P-P @ 8830.7mhz.

If you have close to this time to move on to the RF board. I must say this is getting a little odd as you have good output ini SSB and FSK which tells us you have good TIF level and the TX Mixer on RF Board is working which means you have good VCO (LO to the mixer).

Are you 100% certain you have no CW RF output on all bands? If so, then proceed on to the RF board with Heaters On and SG off and rig peaked as noted above.

You should have close to the values noted on the TX Level Diagram. At Conn RF-1 Pin 10 the 8.830 TIF signal level is approx 38mv rms or 108 P-P.

At output of TX Mixer should have approx 1.5v rms or 4.2v P-P rf drive at MD. At MD frequency will now be 14.175mhz transmit frequency.

If you have no RF drive or very weak at MD then need to measure the VCO level and frequency at RF-1 pin 4 and on board at TP-1. Should be close to 1.0v rms level. If no VCO try on other bands.

We are making good progress. Your Tek 2445 is perfect scope for KW Hybrid work and you apparently know how to use it and can read a schematic and can locate points on these high density boards to take measurements. This really helps.

Based on your report of no RF output in CW mode I would have thought we would have found no TIF sig at output of the IF board. TIF is not band specific and often is caused by no output from the Bal Modulator, This is why I had you start by testing for bias voltage and LO signal available. Never expected that we would be at the RF board and TX Mixer based on good RF output on other modes.

Terry,

I read a little over 700mV at the drain of Q18 (actually the backside of C92 feeding the coax). I think you meant Q18 instead of Q10.

D7 and D8 are the CW switching diodes. With the mode switch in CW position, I have 2.98 volts on the anode of D7 and 2.34 volts on the cathode. I have 10.0 volts on the anode of D8 and 9.40 volts on the cathode. These voltages are there in both RX and TX, just a few 10ths of a volt lower in TX mode.

Can you confirm how the 3 pin cable ofr IF2 is supposed to plug in? It only has 3 wires but there are 5 pins on the IF board at that point. According to the chassis wiring diagram, only the first 3 pins are used as they come from S6-1.

I don't think there is anything wrong with the CW filter and the switching diodes as the CW filter works fine in RX mode.

I have 400mV P-P on Gate 1 of Q1 instead of the 160mV when flipping Send. I also have 2400mV P-P on the drain instead of 1000mV when flipping Send.

TIF signal on Conn IF-3 is 400mV P-P and the sine wave isn't quiet as clean there as it is on the drain of Q1.

Hopefully we are making progress.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Good job. Much better.

If I understand your chart you are telling me that you have approx 640mv P-P @ 8.83077 at TP-5 in CW mode with rig flipped to Send (heaters off and SG switch off). 900mv P-P is attainable by adjusting T1 on CAR-2 board, but can do later unless you want to peak it now. 640mv will work for testing.

If this is true then you have confirmed that you have the two things you need at the Balanced Mod to produce RF output from it in CW mode. 1. Offset bias voltage and 2. Proper Carrier freq and level.

From the BM output the CW signal is routed to the Crystal IF Filter and then to Q1 the Transmit IF Amp or TIF amp. TIF signal leaves the IF board and is routed to the RF board to the TX Mixer where it is mixed with VCO to produce the actual transmit rf drive signal. No TIF signal and there will be no RF drive and no RF output. Also no VCO or low VCO level and no rf drive. Lets validate that we have TIF signal in CW mode first.

Unfortunately KW didnt provide a nice test point at the output of the Balanced Mod to measure the DSBSC signal in SSB mode or the Carrier in CW mode. However, you can get on the Drain of Q10 with a hat pin or floral arrangement pin and mini-grabber test lead. If you locate the BM ring diodes D26-D29 and then output Xfmr T10 you will see Q10. It is a metal can dual gate mosfet. Looking down on the can the Drain is the upper right lead. You should read approx 800mv P-P here. This signal is routed to the Xtal filter thru switcing diodes.

Do you have the CW filter installed. It is rare but could have a bad filter. More common to have a bad switching diode.

After signal passes thru the Xtal filter it is applied to Gate 1 of TIF amp Q1. It is also a metal can dual gate mosfet and sits outside and almost between the two filters at the inboard end. Looking down on Q1 Gate 1 is at 1200. Should have approx 160mv P-P here. The Drain is at 0600 and should have approx 1000mv P-P. TIF output is on Conn IF-3 Pin 2 and should have approx 850mv P-P here. You can jump right to measuring TIF output if you want and if good then off to the RF board.

We know that you have TIF output in FSK mode as you reported good RF output in that mode. I dont kow if you keyed rig in FSK and noted the 170hz shift or not, but not important right now. Also, you should have noted that the RF output in FSK is lower as the 820 lowers the Finals Screen Grid voltage in FSK mode so the tubes plate dissipation is not exceeded in this high duty cycle mode.

That should be enough for now.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

This is what I am seeing:
TP-5 and CJ3-CA2 have the same levels in CW and FSK modes: 820mV P-P in RX mode. Flipping Send switch the level drops to 640mV P-P. I have a Tektronix 2445 Scope and have the probe in 10X to prevent loading the circuit.

Frequencies measured at CJ3-CA2:
RX mode FSK - 8.828414 - TX mode FSK 8.830620
RX mode LSB - 8.828414 - TX mode LSB 8.828579
RX mode USB - 8.831460 - TX mode USB 8.831625
RX mode CW - 8.831460 - TX mode CW 8.830777

Frequencies measured at TP-5:
RX mode FSK - 8.828410 - TX mode FSK 8.830616
RX mode LSB - 8.828410 - TX mode LSB 8.828575
RX mode USB - 8.831450 - TX mode USB 8.831622
RX mode CW - 8.831446 - TX mode CW 8.830773

I am using a Simpson 710 Frequency counter. Specs say 1 Meg input shunted by 30 pF. The slight differences in frequency readings between CJ3-CA2 and TP-5 is probably due to the cable capacitance of the cable between IF5-13 and CJ3-CA2.

I have been taking all of these measurements with the SG switch turned off and the heater switch turned off.

Ray:

I mis-spoke in Item 2 when I said you cant measure carrier at TP-5 in Rx in any of the mode switch positions. There will be legitimate carrier but not of interest.

There will be Carrier at CA-2 and TP-5 in Rx in all positions of the mode switch that you should see, but it is meaningless for CW Tx operation. It was not correct for me to label it as "Leakage" signals.

It is there by design but not for Rx or Tx operation. CA-1 Carrier Osc signals are coupled to the CAR-2 board to amp Q3 and then on to TP-5 at IF board and then sampled and sent to the CCR lead to provide carrier oscillator signals for the Counter Mixer Board. So the carrier osc signals you were measuring at each position of the mode switch in Rx are there by design to feed the counter, but of no interest to us as not utilized for the BM and CW transmit.

So you will see approx 250mv rms at 8831.50 mhz in CW and LSB and 250mv at 8828.5mhz in LSB and FSK, but not used by the BM. BM is not used in Rx operation. So disregard these signal other than the low levels you measured cannot be correct if your counter is working properly. I suspect you are not using O-scope properly. Are you using a 10X probe?

What I meant to say is at CA-2 and TP-5 the only frequency and level we care about is in CW and FSK positions of the mode switch in Tx. CA-2 carrier oscillator should be approx 250mv rms @ 8830.70mhz when in CW and FSK mode when flipped to send. This is what you are trying

to validate. Measure at TP-5 in FSK as you know it is working. So use it to get your O-scope set up correctly and you can see approx 850mv P-P at 8830.7mhz. Once you can read that on your O-scope now switch to CW mode and flip to send to measure carrier osc signal level at TP-5.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Yes this new format gives me problems as well.

1. You are getting proper dc bias voltage to the BM. You need to confirm you are getting the Carrier Osc signal.

2. You cannot measure any Carrier freq or level at TP-5 in RX for any position of the mode switch. You may read some leakage signals in RX mode but meaningless. The BM is only used for TX and not RX. Only time you can measure any meaningful Carrier Osc frequency or level at TP-5 is in TX with the mode switch in CW or FSK. Carrier in RX mode is applied to another Mixer called the Product Detector and it arrives at IF board on IF-4 C1A terminal. You have separate Carrier Oscillators for RX and TX.

Also, the Car Level Pot has nothing to do with the Carrier Osc levels produced on the CAR Assembly Unit. The Car level pot unbalances the balanced modulator and determines the carrier output level from the BM.

You really need to measure CA-2 produced on the CAR-2 board. If you do not have 300mv of 8830.7mhz at TP-5 in CW mode when you flip to Send then you have to work your way back from TP-5 to CAR-2 board. CA2 can be checked on the 7th terminal up on the white terminal block on the CAR-2 board. On the IF board it comes in on Conn IF-5 pin 13.

At this point you have not confirmed that you have CAR-2 Q1 Oscillator running and available.

3. The DC voltages that you measured at D1 prove that you are getting the turn on voltages for Buffer amp Q2 so if Q1 is oscillating should get CW TX Carrier at CJ-3 and on to the IF board if all connectors are good.

You may have to adjust the frequency and output level but can talk about that later.

Suggest you buy a Freq Counter. Can measure Freq roughly with O-scope. Some measure and display Freq (may or may not do so accurately) and some require using F=1/T and not accurate enough for adjusting the Oscillators in the KW hybrids.

Let's try this again. For some reason yahoo has been mangling my posts. This has been a problem ever since they went to this new stupid format they are using.

Measuring at TP-2 the voltage varies from 16 mV to .443V when adjusting the CAR control in both FSK and CW mode. On Conn IF-5 at the CV terminal, the voltage varies from .12V to 8.95V in both FSK and CW mode when adjusting the CAR control.

Also, on the FIX VOX board FIX3-11 is grounded with no key plugged in. Plugging a key in, FIX3-11 follows the key (open key up, grounded key down).

I have cleaned the contacts on the Mode switch and checked for broken wires.

At TP-5 I measure 8.831434 MHz at .64V P-P (on scope) in all positions of the mode switch without the Send switch flipped. When I flip the Send switch the voltage drops to .48V P-P. The CAR control has no affect on the signal level with the Send switch in either position.

I measure 8.97V at the CW terminal on CAR-2 when I flip the Send switch. I measure 8.94V at the anode of D1 and 8.19V at the cathode when the Send switch is flipped.

I have a couple of multimeters, a 150 MHz analog scope, 100 MHz digital scope, W7ZOI power meter, and a KA7EXM power meter. I feel comfortable taking measurements anywhere inside the radio including the Final Cage.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

For some reason I cannot read your entire response? It appears you are reporting back that you have good bias voltage available at the BM from the Car Pot. In CW TX mode you need this bias voltage and you need the local oscillator (LO) or Carrier to produce an output. Which in this case it is 8.830.70mhz CA-2 produced on the CAR-2 Unit.

You are getting CA-2 Carrier in FSK mode so it tells me the Crystal and the soldering at its pins have to be good.

If you have a RF millivolt meter or O-scope you can measure the 8830.7 mhz Carrier at the IF board at TP-5.TP-5 is tucked back in the corner under the chassis side rail. With rig in CW mode flip to send and measure the level and the frequency at TP-5. It should be approx 300mv rms or approx 850mv P-P on a scope at 8830.70mhz.

I would measure the level first before you look at it with a Freq Counter as the counter may pull the level down. If you dont have a means to measure CA-2 Carrier level and frequency then at minimum measure CW terminal at CAR-2 Unit board to make sure you are getting CW TX bias voltage.

If you remove the 2 screws that secure the cover you will see a white 10 pin connector. The 3rd pin from the Crystal is the CW terminal. When you flip to send in CW mode should see approx 9.0vdc here. If you have 9vdc and still no output then suspect bad switching diode D1. D1 is close to the Crystal and you can measure the voltage at its anode and cathode. When you flip to send in CW mode should read approx 9vdc on the anode and approx 8.3vdc on the cathode. Note: The 9vdc will depend on where the AVR regulated 9vdc has been set too.

Ray

I forgot to mention where I am going with this (if not obvious) is a bad/dirty Mode switch contact or a broken wire at the mode switch in CW mode. The fact that you have output in FSK tells me that you do have approx 0.0 to 0.60vdc at TP-2 which then means the path from CV to the BM is good.

If you have no DMM, VOM, or VTVM the mode switch in a TS820 is an open deck type and pretty accessible with bottom cover off so you should be able to apply some deoxit and canned air to clean the contacts.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK well that would have been a quick fix and not first time so had to ask.

What test gear do you have and what is your comfort level to take measurements inside the rig?

When you inject audio into mic line and get output it tells you that your Balanced Modulator is working. In CW mode to produce output from the BM the Car Pot provides variable DC voltage to bias on the ring diodes. It is derives this bias voltage from regulated 9vdc from AVR board thru mode switch contacts.

The BM is on the IF board. Need to measure at Conn IF-5 at the CV terminal. Should see variable 0 to 9vdc at CV as you adjust the Car Pot thru its range.

Then measure at TP-2 and should see approx 0.0 to 0.70vdc as you adjust the Car Pot.

Do you have a key in the key jack? If so remove it or key the key with Car Pot advanced. Cant load rig in CW mode if you have a key in key jack and it isnt closed. Brings back memories of the J-38 slider bar.

We can talk about plate dip not occurring at right place when we get CW working.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

Thanks for the comments.

1) I have 60 ma of current when I flip Send switch in CW, USB, and LSB modes. I don't have a microphone as I only operated CW back when I was on the air. I have a 1KHz tone generator and connected it to the microphone input. When I do this and increase MIC control in both USB and LSB I am able to drive plate current to the same 160 ma (on 20 meters) that I get in the FSK mode. So it appears CW is the only mode that isn't functioning.

2) I tuned the rig to the max power out (IP 160 ma) into the dummy load in the FSK position. I then switch to CW mode but the IP stays at 60 ma. This is with the CAR control at max (10 mark). Bias voltage drops from -100 to -63 volts when I flip Send switch in CW mode.

3) In the FSK mode I get almost FSD with CAR control at max on 20 meters in the ALC position. I am only 2 tick marks away from FSD. On 80, 40, and 160 I am able to get FSD at lower levels of the CAR control. However, when I turn SG back on and tune, the plate dip is in the wrong position for 40 and 160. For both of those bands max dip is at the very low end of 3.5 dial marking. On 20, 15, and 10 the dip is in the correct position. On 10 I am only able to get 80 ma of plate current at min dip with CAR at max. This does indicate the 12BY7 is bad. I think I have a spare one somewhere around here - just have to look. When I switch to USB or LSB I am able to get the same levels of ALC deflection as FSK when I inject the 1 KHz. However, in CW mode I do not get any ALC meter deflection.

4) I will perform this step once the rig is working.

5) I am using the dummy load because I have a 40 meter dipole 8 feet off the ground (HOA) as my only antenna and not sure of the impedance it reflects. I have a Heath HM-15 SWR bridge but it doesn't have a watts reading. I just received an order from Mouser yesterday with the parts to build the dummy load that is on the K4EAA website. I am including the power measurement components so I will be able to know what my power out is. Once I am back on the air I will obtain an inline watt meter.

6) I haven't been on the air in 17 years and am wanting to get back on since I will be retiring in Jan and moving to somewhere that doesn't have a HOA. I have a HW-100 and a FT-101E that have sat in the garage for the last 17 years. I built the HW-100 back in 1968 and last used it in 1986. The FT-101 was working and I was using it on a daily basis when I went QRT at the end 1996. I bought this TS-820 10 years ago but have never used it. It has sat in the closet in my office since I bought it. I figured I would try to get it working first as it hasn't been exposed to extreme temperatures. I would be scared to power the other two up without replacing all the power supply caps first. My garage never drops below 100 four months out of the year.

Very common for jumpers or low value resistor shunted across 470 SG resistor. Owner was "hot rodding" the rig. Higher SG voltage = more RF output power.

It is CB mentality with no understanding of what it takes to get an S-unit difference on the receiving end.

Usually it means they also load to whatever maximum plate current they can. I ohm meter reading of the plate choke wont show much. Do a good visual on it. If windings are discolored sure sign of abuse from a non-thinking person.

You may want to consider replacing the plate coupling/blocking cap and the RF bypass capacitor at the base of the choke and the small VHF choke in series with the main choke given your 10 ohm finding. Ken K4EAA sells a kit.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

I am working on a TS-520S that has its screen grid and cathode resistors burned up. After replacing the resistors I am tracing the screen grid supply back to the rectifier board and found R5 open. Someone who owned the rig many years ago had put a 10 ohm resistor across R5 which probably caused the demise of not only the resistors but has probably caused the final to get "cooked". Evidently whoever owned the rig years ago had a final tube go out and instead of putting the right value resistor in they stuck a 10 ohm resistor in instead.

In studying the schematic in both the owner's and service manuals I found there were 2 R5 resistors, Both are 470 ohm and one is in series with D5 whereas the other R5 goes from the output of the rectifier board (300V) to ground. Is this a misprint?

Is there an easy way of tilting the rectifier board so I can replace the now open R5? Short of disconnecting the wires from the board and taking it out I don't see any way to tilting the board which leads to the fact I will probably have to solder a new 470 ohm resistor across the old one in order to complete the circuit. Once that is done I can proceed with checking the plate choke, doing resistance and the voltage checks with the finals not installed. Once I am satisfied with the readings only then will a new pair of tubes be plugged in.

On a transmitter that the tank capacitor does not have a mechanical stop there will always be a 2nd dip at 180 degrees of plate rotation. This is no concern as it is electrically the exact same amount of capacitance resonating the tank coil. This is normal.

In old Novice days with crystal control it was common to use the plate tank circuit as a frequency multiplier so you could find two dips. One at the fundamental frequency and one at the harmonic (double or triple). So had to be careful that you were on the correct dip to avoid out of band transmission. Had to make a cheat sheet or mark the front panel of the transmitter.

I have never experienced a tank cap 2nd dip on a KW hybrid that resulted in harmonic output.

You can load your TS530 on the 2nd dip on any band. The 2nd dip occurs at 180 degrees of the tank cap plate rotation, but may not be at 180 degrees as indicated on the front panel as there is a reduction drive coupling involved. So on 40 meters 2nd dip might be at 45 degrees ccw and on 20 meters might be at 270 degrees ccw.

Hello-
    I need to touch up and repaint some various TS-520 / 530 cases. Are there any common spray paint colors that match the Kenwood cabinets?
        Thanks, Byron WA5THJ

45465. Ladder line adventures

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-25 16:01:41 UTC
From: Craig Roberts
Topic: 45442 Message: 45465

I recently erected a 55-foot long non -resonant doublet antenna fed by 48 feet of "homebrew" 600 ohm ladder line using #14 insulated wire and "Ladder Snap" spreaders. The dimensions were as recommended by various sources. This single skywire now serves as my all-band (well, 40, 20, 17 and 10 meter) antenna for my TS-530S, TS-830S and accessory AT-230 tuner. It works well and looks cool, steam punk retro.

Here are a couple of "lessons learned" observations about ladder line fed (balanced feedline) antennas for those who, like me, have never used one previously.

#1 Don't bother with a balun between the AT-230 tuner and the feedline. Instead, obtain a dozen Amidon FB-31-5621 ferrite beads and slip them over your small diameter coax jumper between the rig's RF output (antenna) connector and tuner INPUT. If you employ this current balancing method do NOT tie the grounds of the tuner and radio together. (This was not my idea, but one from a highly technical QST article that I read after purchasing an expensive 1:1 high-power current balun that proved to be useless).

#2 Beware of large metallic objects near your ladder line feedline. The avoidance of practices like draping your ladder line over roof gutters and such is intuitive, but you could run into trouble from more subtle sources. For instance, when I initially installed my new antenna/feedline combo, I experienced mysterious reactions from my AT-230. Hand capacitance was affecting power output and SWR readings dramatically. I was suddenly revisiting my earliest days of regen receivers and single wire antennas! Frustrated, I was about to tear down my new antenna and re-erect my coax-fed dipoles when I noticed that the ladder line inside the shack was running just a couple of inches away from a large metal filing cabinet. This thing was so much a part of the room's permanent fixtures that I had ceased to "see" it. Anyway, moving the cabinet to the opposite side of the room cured all anomalies.

While my new doublet can't compete with a Yagi, it does provide multi-band operation with low feedline loss and has proved to be at least as effective as the dipoles in transmission and better in reception.

Try one!

Hi Byron,

An eBay seller offers spray paint in the Kenwood hybrid colors (just do an eBay search for "Kenwood paint." It's not an exact match, but pretty darned close. I used his light gray paint to completely re-do a mildly beat-up TS-830S cabinet top (after stripping to bare metal and prepping the surface). I ended up overspraying the cabinet bottom to match colors precisely, but it was no big deal. After an enjoyable Sunday afternoon's work, the radio new looks new and blends in nicely with the rest of the hybrid lineup.

On 10/24/2013 11:25 AM, Joe - W7RKN wrote:

> Just because you don't see your posts returned to you, rest assured,

Not at all worried or even commenting about my own posts. It is all the OTHER posts, from other members, about 80 percent of them, which are missing in my Inbox. I started getting curious when replies appeared, with copies appended of messages which I had never seen the original.

Using a web browser equipped with a lot of ad-blocking extensions, I went back to the Yahoo site, and started comparing my received messages to the messages listed on that nightmare of a web page.

It's running four or five to one at the moment, missed messages to received, after a sudden mass dump of almost forty email messages appeared, a few days back. Initially it was almost twelve missing for every one received.

If I had to guess, the Yahooligans are attempting to cut out of the herd those of us savvy enough to avoid their incredibly annoying "targeted" advertisement system. (Simply put, those who use an email client program to receive their email, instead of a web browser program. That particular abomination of a kludge has been the bane of my professional existence on more than a few occasions. Besides, my Pop always taught me to use the right tool for every job....)

I suspect they are assuming that people will use the web site, and be force-fed ads. Personally, as much as I learn from this list and the denizens thereof, I'm about >< THAT close to dumping it and removing myself from the list. I don't deal well with such demands. I find them somewhat extortionate, actually. "Use OUR way, or else your email gets it, right in the head!"

> For some reason, Groups does not send your posts back to you, the
> sender. Some of my Groups do, others don't.

"See my own messages" is a setting. it can be toggled on if a user wants unless that is one of the 'features' which the Yahooligans removed in this latest goat-rodeo. Normally the default setting is selectable by the mailing list system administrator at the time a list is set up. Likewise (usually) whether to post replies above or below the original message, as well as including the entire original message.

I wish members here would just learn how to use "Control-A, DELETE" once in awhile for messages which do not require any specific reminders. Just removing ads and extraneous sections of text, leaving a couple of sentences or a paragraph to serve as a reminder of what specific point

they are replying to would be most excellent, but I know that is MUCH too much to ask.

It used to be called "Netiquette" back when we were building this thing known now as the "Internet." "DARPANet" was much more polite and a lot less chaotic, if limitied in scope. Rather (precisely!) like the difference between the Ham bands and Children's Band communications.....

No, I am not in the business of moderating "groups." Instead, I administer (hardware and software) email servers and email list server software installations. For my living, though I am now retired.

But I still run my own systems for these purposes, Unix and Linux machines, using PostFix and MailMan at the moment, but various examples of those kinds of packages over the years. It's just a hobby now. Sort of. Some of the people who use my boxes for their email accounts and web sites send me a little wonga now and then for the upkeep and connection, so I do make something on the deal once in awhile.

(Over the years I have also been responsible for web, file, database, and some other things, even some IRC server nodes at one point. It's just part of the system administrator's job. You have to be flexible and open-minded, willing to learn new tricks now and again. Retaining the use of the OLD tricks is also a good idea. You can be so open-minded that your brain falls out.)

45469. Replacing a VFO-520 with DDS VFO

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-25 16:03:54 UTC
From: <kk6fut@...>
Topic: 45469 Message: 45469

Hi all--

I'm a newbie-newbie (licensed in July - albeit to Extra), so forgive anything that's been asked a billion times before. I have two Kenwood Hybrid rigs (TS-520, TS-820S), the TS-520 is my everyday rig.

Not sure if it will be considered heresy here, but I have recently built (for another ham project) a DDS VFO and it occurred to me that I should be able to replicate the output of the VFO-520 and use this on the 520 (just for kicks...) (yes, I could just go buy a VFO-520...)

With the DDS I can set to output the correct 4.90 to 5.5Mhz I believe is required for replicating the output of a VFO-520 on the frequency generator side (??). However, it's unclear to me what frequencies ought to be fed into the VFO input to replicate the VFO-520--I grew up in the world of microprocessors, so this is probably basic knowledge for all of you.

It looks like the pins on the connector are:
1 - VFO signal
2 - VFO coax ground
3 - lamp indicator (no need to connect) (gnd)
4 - lamp indicator (no need to connect) (12V)
5 - ?? (relay when transmit on from radio, no need to connect?)
6 - ??? (calibrator signal, no need to connect?)
7 - nc
8 - no connect? (was 9v to supply internal VFO -- or should this still be jumpered to 9?)
9 - no connect (9v to external vfo, not needed?)

Has anyone tried this? Any suggestions/thoughts on if this would work at all?

Ben

Dave:

No need for you to bow out. I was trying to help. I will attempt this clarification and then go back to my bench.

I apparently did not explain it well enough. There is a difference between 180 degree rotation of the capacitor plates and 180 degrees rotation of the Pointer indication when a reduction drive (similar to a Jackson drive) is used. If the Plate Tuning cap is directly driven off the shaft knob then there would be 2 dips at 180 degrees of the knob position. Dont want to direct drive a Tank capacitor as it would make tuning resonance touchy.

If you get a dip at the normal band specific white mark location on the front panel and lets say that is at 1200 or North you cannot simply rotate the knob until you are at 0600 or South and expect to find a dip. It will not be there. If that is what the Op is doing or being directed to do he will not find a dip there.

What this fellow should do is make sure that the couplings are all tight and he is not turning the knob and shaft and the air variable is not moving in sync with it. If the couplings are tight and alignment hasnt slipped then he should place rig in Tune mode and flip to Send and find resonance on the white painted arc. He can do this by looking for IP dip, a peak on the RF relative power meter indication or looking at a peak in output power on an external wattmeter. It should be very close to 14 or just slightly to the right side of the "4".

Record or note where that is at. Now key the rig again in Tune mode and rotate the Plate Tune capacitor until you find the other dip. You cannot just turn the knob until the pointer is at 180 degrees from the first "normal" dip location.

In Tune mode you have time to run the Plate Tune knob until you bring the pointer completely back to the original dip without hurting the finals. Somewhere in that travel will be the 2nd dip.

As I tried to point out in my post at approx 14.2 mhz the 1st or normal dip will occur close to 1:00 pm or 1300 and the 2nd dip will occur at approx 5:00 pm or 1700. The 2nd dip will not occur at 7:00 pm or 1900 which would be 180 degrees of pointer rotation.

I saw all this talk about North and South and 180 degrees relative to the Pointer and I wanted to make sure he was not just turning the knob to get the Pointer 180 degrees from the original dip and reporting back no dip at that "south" location.

What I suggest is we ask him to find the "normal"dip and then flip to send again and find the 2nd dip and report back where that occurs at.

You are exactly correct there has to be two dips and they do occur when the air variable has been rotated 180 degrees and the degree of plate mesh is the same and the resulting capacitance is the same. However, that will not occur at 180 degrees of pointer rotation.

If the drive mechanism is working and aligned properly and the Op runs the capacitor thru 360 degrees of rotation and there is no 2nd dip then we have a phenomenon!

You stay and help. I have apparently "helped" enough. Sorry if I did not understand what the Op was doing and reporting. No intention to step on your thread.

Everyone should all be happy I didnt throw in a dose of basic and fundamental crap about air variable capacitor plate shape and linearity and discussion of SLC, SLF, and SLW types. That would really have muddied the waters!

Ron there is just too much crap in the old file cabinet and having hard time finding it anymore. Also need to get control of the fingers that tend to race ahead before I even get the file drawer open.

Young ones will probably do better as their stuff is on the Cloud and they can use key word searches or Find commands!.

Fortunately I can still "Find" my way home most days!

It has been quietly pointed out to me that there is no reduction drive on the TS530 plate tuning capacitor so now we may need to have that SLC and linearity discussion!

I dont have a TS530 here so someone who has one will have to do the "two dip" test and if you find that you do get 2 dips at 180 degrees of rotation of the indicating pointer I will offer my public apology and open the fundamental books for a much needed refresher.

I know that on a TS-830 the 2nd dip does not occur at 180 degrees of pointer indication.

I think I have an old 1930 Cardwell air variable capacitor primer around here some where.

Dave:

No need for you to bow out. I was trying to help. I will attempt this clarification and then go back to my bench.

I apparently did not explain it well enough. There is a difference between 180 degree rotation of the capacitor plates and 180 degrees rotation of the Pointer indication when a reduction drive (similar to a Jackson drive) is used. If the Plate Tuning cap is directly driven off the shaft knob then there would be 2 dips at 180 degrees of the knob position. Dont want to direct drive a Tank capacitor as it would make tuning resonance touchy.

If you get a dip at the normal band specific white mark location on the front panel and lets say that is at 1200 or North you cannot simply rotate the knob until you are at 0600 or South and expect to find a dip. It will not be there. If that is what the Op is doing or being directed to do he will not find a dip there.

What this fellow should do is make sure that the couplings are all tight and he is not turning the knob and shaft and the air variable is not moving in sync with it. If the couplings are tight and alignment hasnt slipped then he should place rig in Tune mode and flip to Send and find resonance on the white painted arc. He can do this by looking for IP dip, a peak on the RF relative power meter indication or looking at a peak in output power on an external wattmeter. It should be very close to 14 or just slightly to the right side of the "4".

Record or note where that is at. Now key the rig again in Tune mode and rotate the Plate Tune capacitor until you find the other dip. You cannot just turn the knob until the pointer is at 180 degrees from the first "normal" dip location.

In Tune mode you have time to run the Plate Tune knob until you bring the pointer completely back to the original dip without hurting the finals. Somewhere in that travel will be the 2nd dip.

As I tried to point out in my post at approx 14.2 mhz the 1st or normal dip will occur close to 1:00 pm or 1300 and the 2nd dip will occur at approx 5:00 pm or 1700. The 2nd dip will not occur at 7:00 pm or 1900 which would be 180 degrees of pointer rotation.

I saw all this talk about North and South and 180 degrees relative to the Pointer and I wanted to make sure he was not just turning the knob to get the Pointer 180 degrees from the original dip and reporting back no dip at that "south" location.

What I suggest is we ask him to find the "normal"dip and then flip to send again and find the 2nd dip and report back where that occurs at.

You are exactly correct there has to be two dips and they do occur when the air variable has been rotated 180 degrees and the degree of plate mesh is the same and the resulting capacitance is the same. However, that will not occur at 180 degrees of pointer rotation.

If the drive mechanism is working and aligned properly and the Op runs the capacitor thru 360 degrees of rotation and there is no 2nd dip then we have a phenomenon!

You stay and help. I have apparently "helped" enough. Sorry if I did not understand what the Op was doing and reporting. No intention to step on your thread.

Everyone should all be happy I didnt throw in a dose of basic and fundamental crap about air variable capacitor plate shape and linearity and discussion of SLC, SLF, and SLW types. That would really have muddied the waters!

Hi Craig,

Better yet, find an old Johnson Match Box!

I bought some commercial ladder line from the Wireman about 10 years ago with the intention of "playing" with it. I made a trade for the Match Box (the small one) with a friend of mine knowing I would need it "someday". I could never get the Match Box to tune coax, though.

Finally last fall I decided to put up as much antenna wire that would fit on my lot. This ended up to being about 175' fed at the center. I think I calculated this to resonate around 2.1 Mhz. I purposely DID NOT want the antenna to be resonate on amateur bands.

The antenna matches beautifully on all bands except 30 meters and I'm loving it!

73,

gary ai4ja

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

I recently erected a 55-foot long non -resonant doublet antenna fed by
48 feet of "homebrew" 600 ohm ladder line using #14 insulated wire and
"Ladder Snap" spreaders. The dimensions were as recommended by various
sources. This single skywire now serves as my all-band (well, 40, 20, 17
and 10 meter) antenna for my TS-530S, TS-830S and accessory AT-230
tuner. It works well and looks cool, steam punk retro.

Here are a couple of "lessons learned" observations about ladder line
fed (balanced feedline) antennas for those who, like me, have never used
one previously.

#1 Don't bother with a balun between the AT-230 tuner and the
feedline. Instead, obtain a dozen Amidon FB-31-5621 ferrite beads and
slip them over your small diameter coax jumper between the rig's RF
output (antenna) connector and tuner INPUT. If you employ this current
balancing method do NOT tie the grounds of the tuner and radio
together. (This was not my idea, but one from a highly technical QST
article that I read after purchasing an expensive 1:1 high-power current
balun that proved to be useless).

#2 Beware of large metallic objects near your ladder line feedline. The
avoidance of practices like draping your ladder line over roof gutters
and such is intuitive, but you could run into trouble from more subtle
sources. For instance, when I initially installed my new
antenna/feedline combo, I experienced mysterious reactions from my
AT-230. Hand capacitance was affecting power output and SWR readings
dramatically. I was suddenly revisiting my earliest days of regen

receivers and single wire antennas! Frustrated, I was about to tear down my new antenna and re-erect my coax-fed dipoles when I noticed that the ladder line inside the shack was running just a couple of inches away from a large metal filing cabinet. This thing was so much a part of the room's permanent fixtures that I had ceased to "see" it. Anyway, moving the cabinet to the opposite side of the room cured all anomalies.

While my new doublet can't compete with a Yagi, it does provide multi-band operation with low feedline loss and has proved to be at least as effective as the dipoles in transmission and better in reception.

Try one!

73,

Craig

With the BAND switch set to 7 MHz or lower, the Digital Display (DG-1) frequency jumps all over the place, at seemingly random frequencies around the band range set with the BAND switch. 14 Mhz and higher are stable, with no symptoms displayed when switched to these bands.

I've double-checked the VFO remote cable for continuity and cleaned the contacts at that point. I also jumpered pins 8 and 9 at the remote VFO port to remove the remote VFO from the equation, but the problem continues.

Is it possible there are dirty contacts at the Display Unit, AVR unit, or Counter Ass'y unit that might cause this? DeoxIT here?

45480. Using contact cleaner, DeoxIT, as general maintenance?

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)

Topic: 45480 Message: 45480

I used DeoxIT to successfully clean the HEAT switch on my TS-820. In your opinion, is it a good idea to use DeoxIT in other areas of the radio just to clean things up a bit? If so, what are the key areas you would spray to clean up if you had a radio that was sitting for a while, or displaying issues of poor contacts?

If not, I understand. Maybe best not to spray the stuff if you don't need to. However, seems like a good idea to clean up some key areas in the radio.

Let me know if you have any maintenance steps you like to go through to clean up one of these radios to ensure clean contact areas.

Terry,

At this point I am using my scope with 1 meg input. If is become suspicious of the reading I switch the 10X on and take the reading that way.

An immediate problem I see is I only have 10mV P-P at the drain of Q1 in FSK mode and 0 output in CW mode. The diagram says there should be 250 mV rms there. If I pull the CW filter out of the radio, how does the CW transmit work? Does the signal then go through the USB filter or do I need to install a jumper where the CW filter was?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Yes they are RMS.

I take them at around 14.175 to 14.200 mhz with the Car Level pot advanced to the point that with the Drive Control adjusted for a peak in ALC indication at panel meter full scale deflection. Then switch to CW mode and load to approx 100 watts out and turn off SG switch. Leave Car Level and Drive control alone.

Measured values will vary depending on what test instrument you are using, length of any test jumper leads used to access the test points, line voltage.

For example 8.830mhz TIF output at the IF board and input at the RF board is shown as 0.038v. This is 38.0 mv rms rf volts or 38 x 2.828 = 107 mv P-P. So if you have approx 100mv P-P TIF you are good.

Output of the TX Mixer is 1.4v rms or 4.0v P-P. This RF drive level is now 14.175 mhz.

If you plan on doing a lot of this work suggest you invest in a RF Millivolt meter. I use a Boonton 92E. I find it loads the circuits less and just easier and faster to use.

Of coures once you get to the 1.4 volts at output of the TX Mixer the old fashioned RF probe and VTVM works great. Just have to use multi-diode probe at plate of Driver tube and control grids of the Finals. I used a Heath 309C and PK-3 probes and a IM-18 VTVM for years and still have them for fall back.

Terry,

Are the transmit levels on page 42 of the service manual correct? Are those RMS values?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Thanks Terry. I have been talking to you since you have been helping. I don't know what made me put Dave on the last message (old age maybe).

I decided to start over from the beginning and go stage by stage this afternoon. This is what I did:
(All measurements taken with Send switch operated and Mode switch in CW position. Also, the measurements are the same in both CW and FSK modes.)

I suspected D1 or L1 was bad on the CAR-II board was bad but that is not the case. I have 720mV on CA2 leaving the CAR-II board in both CW and FSK send modes. I also have 720mV P-P on CA2 (IF5-13) on the IF board. I have 100mV P-P at the coax that connects to C92 on the IF board. On the other end of that coax where it connects to the top of T4 on the IF board I also have 100mV P-P. I would have thought the signal out of Q18 would have been stronger but maybe not.

I have 340mV at the junction of the cathode of D7 and C14 on the IF board. I have 280mV on the side of C14 where it feeds the CW filter. The signal going into the filter measures 8.830755 MHz. I only have 6mV P-P coming out of the crystal filter. Is the crystal filter used for transmit?

I connected the antenna to the radio and 20 meters is open. Tuning in CW signals in USB mode and switching to CW mode drops the signal by about 1 S-Unit when the signal is peaked for max signal in both modes.

Where do I go from here?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Are you talking Dave or Terry ? If someone is helping you off list I can back away as I have a pretty full plate right now.

I am not clear where you are measuring this 40mv P-P signal at?

Before I go I will mention that it is normal to not have a clean sine wave at TIF. It does have harmonic content and it is as you say due to LO mixing action. In this case it is coming from the VCO signal feeding back from the TX Mixer on RF board to the IF board.

This is easy to confirm with a TS-830 as you can easily unplug the VCO cable from the PLL board and the TIF signal will then be a nice clean 8.830mhz sine wave.

Dont worry about the complex waveform. Should still be able to get a reasonably close TIF measurement. It may not match exactly the levels on the TX Level Diagram,but you can compare it to the level you get with FSK carrier oscillator.

I dont use a O-scope to run TX Level diagrams once I get to the output of the TIF amp. I use a Boonton RF Millivolt meter and measure levels in rms and the "dirty" TIF signal presents no problem.

I have a new digital O-scope and it has a variety of digital filters. If I set it for a LP filter with a roll off frequency of 10mhz I can get a pretty clean 8.830 TIF sine wave display.

I dont know the Tek 2445 capability in this regard.

One final reminder is that good TIF signal level of approx 38mv rms or 107mv P-P is based on the premise that you accurately measured CA2 at the iF board of approx 300mv rms or 850mv P-P.

If that signal is not there then you would need to repeat the testing I asked you to do at the Carrier Osc board to confirm the 9vdc CW diode switching voltage is available at D1 and Q2 Buffer amp is being turned on.

I have been providing direction based on your reporting back that you have good CA-2 at Carrier board and good CA-2 at TP-5 on IF board.

If good Level at TP-5 then should have proper level at the wiper of VR-5 on the Balanced Mod. As we have discussed. No dc bias from CV and no Carrier at wiper of VR-5 then no output from the Bal Modulator.

I am pretty confident that you do have proper bias voltage from CCW to full CW on the Car Pot, but I am not certain yet that you have proper carrier output from the BM in CW mode.

Good luck.

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Dave,

I have VFO set to 14.175. With Car pot at 1200, in CW mode I get 40mV P-P in RX mode. When I flip the Send switch, the signal stays at 40 mV but it is no longer a sine wave. It is some kind of more or less sine wave with a lot of noise on it. With the Car pot at max, the noisy sinewave increases to 60 mV P-P in Send mode.

In FSK mode with Car at 1200 I get 250mV P-P in Send mode. With Car at Max I get 800 mV P-P in Send mode.

At Conn RF1-10 I get 140mV P-P in CW Send mode. I get 800mV P-P in FSK Send mode.

At the mixer output (Q1 and Q8 side of C8) I get 100 mV P-P in CW Send mode. I get 1V P-P in FSK Send mode. The signal at that point is not a sinewave but seems to have multiple signals. Probably some LO feedthrough on the mixer. The frequency counter agrees with the Kendwood readout as 14.1748 MHz.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Sorry about Q10 vs Q18. My fingers work better than what is left of my brain.

The 3 conductor plug should be positioned in forward position toward the front panel.

One thing we did not talk about is whereiyou should have the Car Level Pot set to take these measurements.

The TX Level Diagram is shown in the Service Manual. These levels were taken by Kenwood by loading the rig to approx 100 watts out at 14.175mhz and then turn the SG switch off and leave Car pot alone and Drive control alone.

Since you have no RF output in CW mode I suggest you do this for remainder of the readings:

1. VFO 14.175
2. Peak the Drive Control on receiver noise or the marker signal
3. Car Level Pot 1200
4. Heater on
5. SG switch off
6. Flip to Send to take RF drive levels

So the differences in voltages may be due to where we each have our Car Level pot set at.

Suggest you measure the voltage and frequency of the TIF signal at IF-3 Pin 2 one more time and it should be approx 250mv rms or 700mv P-P @ 8830.7mhz.

If you have close to this time to move on to the RF board. I must say this is getting a little odd as you have good output ini SSB and FSK which tells us you have good TIF level and the TX Mixer on RF Board is working which means you have good VCO (LO to the mixer).

Are you 100% certain you have no CW RF output on all bands? If so, then proceed on to the RF board with Heaters On and SG off and rig peaked as noted above.

You should have close to the values noted on the TX Level Diagram. At Conn RF-1 Pin 10 the 8.830 TIF signal level is approx 38mv rms or 108 P-P.

At output of TX Mixer should have approx 1.5v rms or 4.2v P-P rf drive at MD. At MD frequency will now be 14.175mhz transmit frequency.

If you have no RF drive or very weak at MD then need to measure the VCO level and frequency at RF-1 pin 4 and on board at TP-1. Should be close to 1.0v rms level. If no VCO try on other bands.

We are making good progress. Your Tek 2445 is perfect scope for KW Hybrid work and you apparently know how to use it and can read a schematic and can locate points on these high density boards to take measurements. This really helps.

Based on your report of no RF output in CW mode I would have thought we would have found no TIF sig at output of the IF board. TIF is not band specific and often is caused by no output from the Bal Modulator, This is why I had you start by testing for bias voltage and LO signal available. Never expected that we would be at the RF board and TX Mixer based on good RF output on other modes.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I read a little over 700mV at the drain of Q18 (actually the backside of C92 feeding the coax). I think you meant Q18 instead of Q10.

D7 and D8 are the CW switching diodes. With the mode switch in CW position, I have 2.98 volts on the anode of D7 and 2.34 volts on the cathode. I have 10.0 volts on the anode of D8 and 9.40 volts on the cathode. These voltages are there in both RX and TX, just a few 10ths of a volt lower in TX mode.

Can you confirm how the 3 pin cable ofr IF2 is supposed to plug in? It only has 3 wires but there are 5 pins on the IF board at that point. According to the chassis wiring diagram, only the first 3 pins are used as they come from S6-1.

I don't think there is anything wrong with the CW filter and the switching diodes as the CW filter works fine in RX mode.

I have 400mV P-P on Gate 1 of Q1 instead of the 160mV when flipping Send. I also have 2400mV P-P on the drain instead of 1000mV when flipping Send.

TIF signal on Conn IF-3 is 400mV P-P and the sine wave isn't quiet as clean there as it is on the drain of Q1.

Hopefully we are making progress.

Ray:

Good job. Much better.

If I understand your chart you are telling me that you have approx 640mv P-P @ 8.83077 at TP-5 in CW mode with rig flipped to Send (heaters off and SG switch off). 900mv P-P is attainable by adjusting T1 on CAR-2 board, but can do later unless you want to peak it now. 640mv will work for testing.

If this is true then you have confirmed that you have the two things you need at the Balanced Mod to produce RF output from it in CW mode. 1. Offset bias voltage and 2. Proper Carrier freq and level.

From the BM output the CW signal is routed to the Crystal IF Filter and then to Q1 the Transmit IF Amp or TIF amp. TIF signal leaves the IF board and is routed to the RF board to the TX Mixer where it is mixed with VCO to produce the actual transmit rf drive signal. No TIF signal and there will be no RF drive and no RF output. Also no VCO or low VCO level and no rf drive. Lets validate that we have TIF signal in CW mode first.

Unfortunately KW didnt provide a nice test point at the output of the Balanced Mod to measure the DSBSC signal in SSB mode or the Carrier in CW mode. However, you can get on the Drain of Q10 with a hat pin or floral arrangement pin and mini-grabber test lead. If you locate the BM ring diodes D26-D29 and then output Xfmr T10 you will see Q10. It is a metal can dual gate mosfet. Looking down on the can the Drain is the upper right lead. You should read approx 800mv P-P here. This signal is routed to the Xtal filter thru switcing diodes.

Do you have the CW filter installed. It is rare but could have a bad filter. More common to have a bad switching diode.

After signal passes thru the Xtal filter it is applied to Gate 1 of TIF amp Q1. It is also a metal can dual gate mosfet and sits outside and almost between the two filters at the inboard end. Looking down on Q1 Gate 1 is at 1200. Should have approx 160mv P-P here. The Drain is at 0600 and should have approx 1000mv P-P. TIF output is on Conn IF-3 Pin 2 and should have approx 850mv P-P here. You can jump right to measuring TIF output if you want and if good then off to the RF board.

We know that you have TIF output in FSK mode as you reported good RF output in that mode. I dont kow if you keyed rig in FSK and noted the 170hz shift or not, but not important right now. Also, you should have noted that the RF output in FSK is lower as the 820 lowers the Finals Screen Grid voltage in FSK mode so the tubes plate dissipation is not exceeded in this high duty cycle mode.

That should be enough for now.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

This is what I am seeing:
TP-5 and CJ3-CA2 have the same levels in CW and FSK modes: 820mV P-P in RX mode. Flipping Send switch the level drops to 640mV P-P. I have a Tektronix 2445 Scope and have the probe in 10X to prevent loading the circuit.

Frequencies measured at CJ3-CA2:
RX mode FSK - 8.828414 - TX mode FSK 8.830620
RX mode LSB - 8.828414 - TX mode LSB 8.828579
RX mode USB - 8.831460 - TX mode USB 8.831625
RX mode CW - 8.831460 - TX mode CW 8.830777

Frequencies measured at TP-5:
RX mode FSK - 8.828410 - TX mode FSK 8.830616
RX mode LSB - 8.828410 - TX mode LSB 8.828575
RX mode USB - 8.831450 - TX mode USB 8.831622
RX mode CW - 8.831446 - TX mode CW 8.830773

I am using a Simpson 710 Frequency counter. Specs say 1 Meg input shunted by 30 pF. The slight differences in frequency readings between CJ3-CA2 and TP-5 is probably due to the cable capacitance of the cable between IF5-13 and CJ3-CA2.

I have been taking all of these measurements with the SG switch turned off and the heater switch turned off.

Ray:

I mis-spoke in Item 2 when I said you cant measure carrier at TP-5 in Rx in any of the mode switch positions. There will be legitimate carrier but not of interest.

There will be Carrier at CA-2 and TP-5 in Rx in all positions of the mode switch that you should see, but it is meaningless for CW Tx operation. It was not correct for me to label it as "Leakage" signals.

It is there by design but not for Rx or Tx operation. CA-1 Carrier Osc signals are coupled to the CAR-2 board to amp Q3 and then on to TP-5 at IF board and then sampled and sent to the CCR lead to provide carrier oscillator signals for the Counter Mixer Board. So the carrier osc signals you were measuring at each position of the mode switch in Rx are there by design to feed the counter, but of no interest to us as not utilized for the BM and CW transmit.

So you will see approx 250mv rms at 8831.50 mhz in CW and LSB and 250mv at 8828.5mhz in LSB and FSK, but not used by the BM. BM is not used in Rx operation. So disregard these signal other than the low levels you measured cannot be correct if your counter is working properly. I suspect you are not using O-scope properly. Are you using a 10X probe?

What I meant to say is at CA-2 and TP-5 the only frequency and level we care about is in CW and FSK positions of the mode switch in Tx. CA-2 carrier oscillator should be approx 250mv rms @ 8830.70mhz when in CW and FSK mode when flipped to send. This is what you are trying to validate. Measure at TP-5 in FSK as you know it is working. So use it to get your O-scope set up correctly and you can see approx 850mv P-P at 8830.7mhz. Once you can read that on your O-scope now switch to CW mode and flip to send to measure carrier osc signal level at TP-5.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Yes this new format gives me problems as well.

1. You are getting proper dc bias voltage to the BM. You need to confirm you are getting the Carrier Osc signal.

2. You cannot measure any Carrier freq or level at TP-5 in RX for any position of the mode switch. You may read some leakage signals in RX mode but meaningless. The BM is only used for TX and not RX. Only time you can measure any meaningful Carrier Osc frequency or level at TP-5 is in TX with the mode switch in CW or FSK. Carrier in RX mode is applied to another Mixer called the Product Detector and it arrives at IF board on IF-4 C1A terminal. You have separate Carrier Oscillators for RX and TX.

Also, the Car Level Pot has nothing to do with the Carrier Osc levels produced on the CAR Assembly Unit. The Car level pot unbalances the balanced modulator and determines the carrier output level from the BM.

You really need to measure CA-2 produced on the CAR-2 board. If you do not have 300mv of 8830.7mhz at TP-5 in CW mode when you flip to Send then you have to work your way back from TP-5 to CAR-2 board. CA2 can be checked on the 7th terminal up on the white terminal block on the CAR-2 board. On the IF board it comes in on Conn IF-5 pin 13.

At this point you have not confirmed that you have CAR-2 Q1 Oscillator running and available.

3. The DC voltages that you measured at D1 prove that you are getting the turn on voltages for Buffer amp Q2 so if Q1 is oscillating should get CW TX Carrier at CJ-3 and on to the IF board if all connectors are good.

You may have to adjust the frequency and output level but can talk about that later.

Suggest you buy a Freq Counter. Can measure Freq roughly with O-scope. Some measure and display Freq (may or may not do so accurately) and some require using F=1/T and not accurate enough for adjusting the Oscillators in the KW hybrids.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Let's try this again. For some reason yahoo has been mangling my posts. This has been a problem ever since they went to this new stupid format they are using.

Measuring at TP-2 the voltage varies from 16 mV to .443V when adjusting the CAR control in both FSK and CW mode. On Conn IF-5 at the CV terminal, the voltage varies from .12V to 8.95V in both FSK and CW mode when adjusting the CAR control.

Also, on the FIX VOX board FIX3-11 is grounded with no key plugged in. Plugging a key in, FIX3-11 follows the key (open key up, grounded key down).

I have cleaned the contacts on the Mode switch and checked for broken wires.

At TP-5 I measure 8.831434 MHz at .64V P-P (on scope) in all positions of the mode switch without the Send switch flipped. When I flip the Send switch the voltage drops to .48V P-P. The CAR control has no affect on the signal level with the Send switch in either position.

I measure 8.97V at the CW terminal on CAR-2 when I flip the Send switch. I measure 8.94V at the anode of D1 and 8.19V at the cathode when the Send switch is flipped.

I have a couple of multimeters, a 150 MHz analog scope, 100 MHz digital scope, W7ZOI power meter, and a KA7EXM power meter. I feel comfortable taking measurements anywhere inside the radio including the Final Cage.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

For some reason I cannot read your entire response? It appears you are reporting back that you have good bias voltage available at the BM from the Car Pot. In CW TX mode you need this bias voltage and you need the local oscillator (LO) or Carrier to produce an output. Which in this case it is 8.830.70mhz CA-2 produced on the CAR-2 Unit.

You are getting CA-2 Carrier in FSK mode so it tells me the Crystal and the soldering at its pins have to be good.

If you have a RF millivolt meter or O-scope you can measure the 8830.7 mhz Carrier at the IF board at TP-5.TP-5 is tucked back in the corner under the chassis side rail. With rig in CW mode flip to send and measure the level and the frequency at TP-5. It should be approx 300mv rms or approx 850mv P-P on a scope at 8830.70mhz.

I would measure the level first before you look at it with a Freq Counter as the counter may pull the level down. If you dont have a means to measure CA-2 Carrier level and frequency then at minimum measure CW terminal at CAR-2 Unit board to make sure you are getting CW TX bias voltage.

If you remove the 2 screws that secure the cover you will see a white 10 pin connector. The 3rd pin from the Crystal is the CW terminal. When you flip to send in CW mode should see approx 9.0vdc here. If you have 9vdc and still no output then suspect bad switching diode D1. D1 is close to the Crystal and you can measure the voltage at its anode and cathode. When you flip to send in CW mode should read approx 9vdc on the anode and approx 8.3vdc on the cathode. Note: The 9vdc will depend on where the AVR regulated 9vdc has been set too.

Ray

I forgot to mention where I am going with this (if not obvious) is a bad/dirty Mode switch contact or a broken wire at the mode switch in CW mode. The fact that you have output in FSK tells me that you do have approx 0.0 to 0.60vdc at TP-2 which then means the path from CV to the BM is good.

If you have no DMM, VOM, or VTVM the mode switch in a TS820 is an open deck type and pretty accessible with bottom cover off so you should be able to apply some deoxit and canned air to clean the contacts.

Terry K9TW

OK well that would have been a quick fix and not first time so had to ask.

What test gear do you have and what is your comfort level to take measurements inside the rig?

When you inject audio into mic line and get output it tells you that your Balanced Modulator is working. In CW mode to produce output from the BM the Car Pot provides variable DC voltage to bias on the ring diodes. It is derives this bias voltage from regulated 9vdc from AVR board thru mode switch contacts.

The BM is on the IF board. Need to measure at Conn IF-5 at the CV terminal. Should see variable 0 to 9vdc at CV as you adjust the Car Pot thru its range.

Then measure at TP-2 and should see approx 0.0 to 0.70vdc as you adjust the Car Pot.

No problem. I wanted someone to take over as I can't see how there could not be two dips. (provided that the variable capacitor on the 530 is the continuous type!)

"If the drive mechanism is working and aligned properly and the Op runs the capacitor thru 360 degrees of rotation and there is no 2nd dip then we have a phenomenon!"

My understanding of the reported problem is just that!

Cheers

From: <rcbuckiii@...>
Topic: 45375 Message: 45484

Terry,

I have made a discovery that will probably tell us where the actual problem is. I was googling how to replace CW filter and found this link:
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2

So I downloaded the operators manual and looked at page 34. Kenwood is perfectly clear about this. If the plug is in position A, the CW filter is bypassed.

I put the plug in position A and can tune to full power out in CW mode. If I place the plug in position B or C I get no power out when in CW mode.

Does this indicate a bad CW filter? The filter works fine in receive mode. The only thing I have noticed is that if I switch from USB to CW the signal drops 1 S-unit when peaked for max signal in both modes.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

At this point I am using my scope with 1 meg input. If is become suspicious of the reading I switch the 10X on and take the reading that way.

An immediate problem I see is I only have 10mV P-P at the drain of Q1 in FSK mode and 0 output in CW mode. The diagram says there should be 250 mV rms there. If I pull the CW filter out of the radio, how does the CW transmit work? Does the signal then go through the USB filter or do I need to install a jumper where the CW filter was?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Yes they are RMS.

I take them at around 14.175 to 14.200 mhz with the Car Level pot advanced to the point that with the Drive Control adjusted for a peak in ALC indication at panel meter full scale deflection. Then switch to CW mode and load to approx 100 watts out and turn off SG switch. Leave Car Level and Drive control alone.

Measured values will vary depending on what test instrument you are using, length of any test jumper leads used to access the test points, line voltage.

For example 8.830mhz TIF output at the IF board and input at the RF board is shown as 0.038v. This is 38.0 mv rms rf volts or 38 x 2.828 = 107 mv P-P. So if you have approx 100mv P-P TIF you are good.

Output of the TX Mixer is 1.4v rms or 4.0v P-P. This RF drive level is now 14.175 mhz.

If you plan on doing a lot of this work suggest you invest in a RF Millivolt meter. I use a Boonton 92E. I find it loads the circuits less and just easier and faster to use.

Of coures once you get to the 1.4 volts at output of the TX Mixer the old fashioned RF probe and VTVM works great. Just have to use multi-diode probe at plate of Driver tube and control grids of the Finals. I used a Heath 309C and PK-3 probes and a IM-18 VTVM for years and still have them for fall back.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Thanks Terry. I have been talking to you since you have been helping. I don't know what made me put Dave on the last message (old age maybe).

I decided to start over from the beginning and go stage by stage this afternoon. This is what I did:
(All measurements taken with Send switch operated and Mode switch in CW position. Also, the measurements are the same in both CW and FSK modes.)

I suspected D1 or L1 was bad on the CAR-II board was bad but that is not the case. I have 720mV on CA2 leaving the CAR-II board in both CW and FSK send modes. I also have 720mV P-P on CA2 (IF5-13) on the IF board. I have 100mV P-P at the coax that connects to C92 on the IF board. On the other end of that coax where it connects to the top of T4 on the IF board I also have 100mV P-P. I would have thought the signal out of Q18 would have been stronger but maybe not.

I have 340mV at the junction of the cathode of D7 and C14 on the IF board. I have 280mV on the side of C14 where it feeds the CW filter. The signal going into the filter measures 8.830755 MHz. I only have 6mV P-P coming out of the crystal filter. Is the crystal filter used for transmit?

I connected the antenna to the radio and 20 meters is open. Tuning in CW signals in USB mode and switching to CW mode drops the signal by about 1 S-Unit when the signal is peaked for max signal in both modes.

Where do I go from here?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Are you talking Dave or Terry ? If someone is helping you off list I can back away as I have a pretty full plate right now.

I am not clear where you are measuring this 40mv P-P signal at?

Before I go I will mention that it is normal to not have a clean sine wave at TIF. It does have harmonic content and it is as you say due to LO mixing action. In this case it is coming from the VCO signal feeding back from the TX Mixer on RF board to the IF board.

This is easy to confirm with a TS-830 as you can easily unplug the VCO cable from the PLL board and the TIF signal will then be a nice clean 8.830mhz sine wave.

Dont worry about the complex waveform. Should still be able to get a reasonably close TIF measurement. It may not match exactly the levels on the TX Level Diagram,but you can compare it to the level you get with FSK carrier oscillator.

I dont use a O-scope to run TX Level diagrams once I get to the output of the TIF amp. I use a Boonton RF Millivolt meter and measure levels in rms and the "dirty" TIF signal presents no problem.

I have a new digital O-scope and it has a variety of digital filters. If I set it for a LP filter with a roll off frequency of 10mhz I can get a pretty clean 8.830 TIF sine wave display.

I dont know the Tek 2445 capability in this regard.

One final reminder is that good TIF signal level of approx 38mv rms or 107mv P-P is based on the premise that you accurately measured CA2 at the iF board of approx 300mv rms or 850mv P-P.

If that signal is not there then you would need to repeat the testing I asked you to do at the Carrier Osc board to confirm the 9vdc CW diode switching voltage is available at D1 and Q2 Buffer amp is being turned on.

I have been providing direction based on your reporting back that you have good CA-2 at Carrier board and good CA-2 at TP-5 on IF board.

If good Level at TP-5 then should have proper level at the wiper of VR-5 on the Balanced Mod. As we have discussed. No dc bias from CV and no Carrier at wiper of VR-5 then no output from the Bal Modulator.

I am pretty confident that you do have proper bias voltage from CCW to full CW on the Car Pot, but I am not certain yet that you have proper carrier output from the BM in CW mode.

Good luck.

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Dave,

I have VFO set to 14.175. With Car pot at 1200, in CW mode I get 40mV P-P in RX mode. When I flip the Send switch, the signal stays at 40 mV but it is no longer a sine wave. It is some kind of more or less sine wave with a lot of noise on it. With the Car pot at max, the noisy sinewave increases to 60 mV P-P in Send mode.

In FSK mode with Car at 1200 I get 250mV P-P in Send mode. With Car at Max I get 800 mV P-P in Send mode.

At Conn RF1-10 I get 140mV P-P in CW Send mode. I get 800mV P-P in FSK Send mode.

At the mixer output (Q1 and Q8 side of C8) I get 100 mV P-P in CW Send mode. I get 1V P-P in FSK Send mode. The signal at that point is not a sinewave but seems to have multiple signals. Probably some LO feedthrough on the mixer. The frequency counter agrees with the Kendwood readout as 14.1748 MHz.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Sorry about Q10 vs Q18. My fingers work better than what is left of my brain.

The 3 conductor plug should be positioned in forward position toward the front panel.

One thing we did not talk about is whereiyou should have the Car Level Pot set to take these measurements.

The TX Level Diagram is shown in the Service Manual. These levels were taken by Kenwood by loading the rig to approx 100 watts out at 14.175mhz and then turn the SG switch off and leave Car pot alone and Drive control alone.

Since you have no RF output in CW mode I suggest you do this for remainder of the readings:

1. VFO 14.175
2. Peak the Drive Control on receiver noise or the marker signal
3. Car Level Pot 1200
4. Heater on
5. SG switch off
6. Flip to Send to take RF drive levels

So the differences in voltages may be due to where we each have our Car Level pot set at.

Suggest you measure the voltage and frequency of the TIF signal at IF-3 Pin 2 one more time and it should be approx 250mv rms or 700mv P-P @ 8830.7mhz.

If you have close to this time to move on to the RF board. I must say this is getting a little odd as you have good output ini SSB and FSK which tells us you have good TIF level and the TX Mixer on RF Board is working which means you have good VCO (LO to the mixer).

Are you 100% certain you have no CW RF output on all bands? If so, then proceed on to the RF board with Heaters On and SG off and rig peaked as noted above.

You should have close to the values noted on the TX Level Diagram. At Conn RF-1 Pin 10 the 8.830 TIF signal level is approx 38mv rms or 108 P-P.

At output of TX Mixer should have approx 1.5v rms or 4.2v P-P rf drive at MD. At MD frequency will now be 14.175mhz transmit frequency.

If you have no RF drive or very weak at MD then need to measure the VCO level and frequency at RF-1 pin 4 and on board at TP-1. Should be close to 1.0v rms level. If no VCO try on other bands.

We are making good progress. Your Tek 2445 is perfect scope for KW Hybrid work and you apparently know how to use it and can read a schematic and can locate points on these high density boards to take measurements. This really helps.

Based on your report of no RF output in CW mode I would have thought we would have found no TIF sig at output of the IF board. TIF is not band specific and often is caused by no output from the Bal Modulator, This is why I had you start by testing for bias voltage and LO signal available. Never expected that we would be at the RF board and TX Mixer based on good RF output on other modes.

Terry,

I read a little over 700mV at the drain of Q18 (actually the backside of C92 feeding the coax). I think you meant Q18 instead of Q10.

D7 and D8 are the CW switching diodes. With the mode switch in CW position, I have 2.98 volts on the anode of D7 and 2.34 volts on the cathode. I have 10.0 volts on the anode of D8 and 9.40 volts on the cathode. These voltages are there in both RX and TX, just a few 10ths of a volt lower in TX mode.

Can you confirm how the 3 pin cable ofr IF2 is supposed to plug in? It only has 3 wires but there are 5 pins on the IF board at that point. According to the chassis wiring diagram, only the first 3 pins are used as they come from S6-1.

I don't think there is anything wrong with the CW filter and the switching diodes as the CW filter works fine in RX mode.

I have 400mV P-P on Gate 1 of Q1 instead of the 160mV when flipping Send. I also have 2400mV P-P on the drain instead of 1000mV when flipping Send.

TIF signal on Conn IF-3 is 400mV P-P and the sine wave isn't quiet as clean there as it is on the drain of Q1.

Hopefully we are making progress.

Ray:

Good job. Much better.

If I understand your chart you are telling me that you have approx 640mv P-P @ 8.83077 at TP-5 in CW mode with rig flipped to Send (heaters off and SG switch off). 900mv P-P is attainable by adjusting T1 on CAR-2 board, but can do later unless you want to peak it now. 640mv will work for testing.

If this is true then you have confirmed that you have the two things you need at the Balanced Mod to produce RF output from it in CW mode. 1. Offset bias voltage and 2. Proper Carrier freq and level.

From the BM output the CW signal is routed to the Crystal IF Filter and then to Q1 the Transmit IF Amp or TIF amp. TIF signal leaves the IF board and is routed to the RF board to the TX Mixer where it is mixed with VCO to produce the actual transmit rf drive signal. No TIF signal and there will be no RF drive and no RF output. Also no VCO or low VCO level and no rf drive. Lets validate that we have TIF signal in CW mode first.

Unfortunately KW didnt provide a nice test point at the output of the Balanced Mod to measure the DSBSC signal in SSB mode or the Carrier in CW mode. However, you can get on the Drain of Q10 with a hat pin or floral arrangement pin and mini-grabber test lead. If you locate the BM ring diodes D26-D29 and then output Xfmr T10 you will see Q10. It is a metal can dual gate mosfet. Looking down on the can the Drain is the upper right lead. You should read approx 800mv P-P here. This signal is routed to the Xtal filter thru switcing diodes.

Do you have the CW filter installed. It is rare but could have a bad filter. More common to have a bad switching diode.

After signal passes thru the Xtal filter it is applied to Gate 1 of TIF amp Q1. It is also a metal can dual gate mosfet and sits outside and almost between the two filters at the inboard end. Looking down on Q1 Gate 1 is at 1200. Should have approx 160mv P-P here. The Drain is at 0600 and should have approx 1000mv P-P. TIF output is on Conn IF-3 Pin 2 and should have approx 850mv P-P here. You can jump right to measuring TIF output if you want and if good then off to the RF board.

We know that you have TIF output in FSK mode as you reported good RF output in that mode. I dont kow if you keyed rig in FSK and noted the 170hz shift or not, but not important right now. Also, you should have noted that the RF output in FSK is lower as the 820 lowers the Finals Screen Grid voltage in FSK mode so the tubes plate dissipation is not exceeded in this high duty cycle mode.

That should be enough for now.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

This is what I am seeing:
TP-5 and CJ3-CA2 have the same levels in CW and FSK modes: 820mV P-P in RX mode. Flipping Send switch the level drops to 640mV P-P. I have a Tektronix 2445 Scope and have the probe in 10X to prevent loading the circuit.

Frequencies measured at CJ3-CA2:
RX mode FSK - 8.828414 - TX mode FSK 8.830620
RX mode LSB - 8.828414 - TX mode LSB 8.828579
RX mode USB - 8.831460 - TX mode USB 8.831625
RX mode CW - 8.831460 - TX mode CW 8.830777

Frequencies measured at TP-5:
RX mode FSK - 8.828410 - TX mode FSK 8.830616
RX mode LSB - 8.828410 - TX mode LSB 8.828575
RX mode USB - 8.831450 - TX mode USB 8.831622
RX mode CW - 8.831446 - TX mode CW 8.830773

I am using a Simpson 710 Frequency counter. Specs say 1 Meg input shunted by 30 pF. The slight differences in frequency readings between CJ3-CA2 and TP-5 is probably due to the

cable capacitance of the cable between IF5-13 and CJ3-CA2.

I have been taking all of these measurements with the SG switch turned off and the heater switch turned off.

Ray:

I mis-spoke in Item 2 when I said you cant measure carrier at TP-5 in Rx in any of the mode switch positions. There will be legitimate carrier but not of interest.

There will be Carrier at CA-2 and TP-5 in Rx in all positions of the mode switch that you should see, but it is meaningless for CW Tx operation. It was not correct for me to label it as "Leakage" signals.

It is there by design but not for Rx or Tx operation. CA-1 Carrier Osc signals are coupled to the CAR-2 board to amp Q3 and then on to TP-5 at IF board and then sampled and sent to the CCR lead to provide carrier oscillator signals for the Counter Mixer Board. So the carrier osc signals you were measuring at each position of the mode switch in Rx are there by design to feed the counter, but of no interest to us as not utilized for the BM and CW transmit.

So you will see approx 250mv rms at 8831.50 mhz in CW and LSB and 250mv at 8828.5mhz in LSB and FSK, but not used by the BM. BM is not used in Rx operation. So disregard these signal other than the low levels you measured cannot be correct if your counter is working properly. I suspect you are not using O-scope properly. Are you using a 10X probe?

What I meant to say is at CA-2 and TP-5 the only frequency and level we care about is in CW and FSK positions of the mode switch in Tx. CA-2 carrier oscillator should be approx 250mv rms @ 8830.70mhz when in CW and FSK mode when flipped to send. This is what you are trying to validate. Measure at TP-5 in FSK as you know it is working. So use it to get your O-scope set up correctly and you can see approx 850mv P-P at 8830.7mhz. Once you can read that on your O-scope now switch to CW mode and flip to send to measure carrier osc signal level at TP-5.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Yes this new format gives me problems as well.

1. You are getting proper dc bias voltage to the BM. You need to confirm you are getting the Carrier Osc signal.

2. You cannot measure any Carrier freq or level at TP-5 in RX for any position of the mode switch. You may read some leakage signals in RX mode but meaningless. The BM is only used for TX and not RX. Only time you can measure any meaningful Carrier Osc frequency or level at TP-5 is in TX with the mode switch in CW or FSK. Carrier in RX mode is applied to another Mixer called the Product Detector and it arrives at IF board on IF-4 C1A terminal. You have separate Carrier Oscillators for RX and TX.

Also, the Car Level Pot has nothing to do with the Carrier Osc levels produced on the CAR Assembly Unit. The Car level pot unbalances the balanced modulator and determines the carrier output level from the BM.

You really need to measure CA-2 produced on the CAR-2 board. If you do not have 300mv of 8830.7mhz at TP-5 in CW mode when you flip to Send then you have to work your way back from TP-5 to CAR-2 board. CA2 can be checked on the 7th terminal up on the white terminal block on the CAR-2 board. On the IF board it comes in on Conn IF-5 pin 13.

At this point you have not confirmed that you have CAR-2 Q1 Oscillator running and available.

3. The DC voltages that you measured at D1 prove that you are getting the turn on voltages for Buffer amp Q2 so if Q1 is oscillating should get CW TX Carrier at CJ-3 and on to the IF board if all connectors are good.

You may have to adjust the frequency and output level but can talk about that later.

Suggest you buy a Freq Counter. Can measure Freq roughly with O-scope. Some measure and display Freq (may or may not do so accurately) and some require using F=1/T and not accurate enough for adjusting the Oscillators in the KW hybrids.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Let's try this again. For some reason yahoo has been mangling my posts. This has been a problem ever since they went to this new stupid format they are using.

Measuring at TP-2 the voltage varies from 16 mV to .443V when adjusting the CAR control in both FSK and CW mode. On Conn IF-5 at the CV terminal, the voltage varies from .12V to 8.95V in both FSK and CW mode when adjusting the CAR control.

Also, on the FIX VOX board FIX3-11 is grounded with no key plugged in. Plugging a key in, FIX3-11 follows the key (open key up, grounded key down).

I have cleaned the contacts on the Mode switch and checked for broken wires.

At TP-5 I measure 8.831434 MHz at .64V P-P (on scope) in all positions of the mode switch without the Send switch flipped. When I flip the Send switch the voltage drops to .48V P-P. The CAR control has no affect on the signal level with the Send switch in either position.

I measure 8.97V at the CW terminal on CAR-2 when I flip the Send switch. I measure 8.94V at the anode of D1 and 8.19V at the cathode when the Send switch is flipped.

I have a couple of multimeters, a 150 MHz analog scope, 100 MHz digital scope, W7ZOI power meter, and a KA7EXM power meter. I feel comfortable taking measurements anywhere inside the radio including the Final Cage.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

For some reason I cannot read your entire response? It appears you are reporting back that you have good bias voltage available at the BM from the Car Pot. In CW TX mode you need

this bias voltage and you need the local oscillator (LO) or Carrier to produce an output. Which in this case it is 8.830.70mhz CA-2 produced on the CAR-2 Unit.

You are getting CA-2 Carrier in FSK mode so it tells me the Crystal and the soldering at its pins have to be good.

If you have a RF millivolt meter or O-scope you can measure the 8830.7 mhz Carrier at the IF board at TP-5.TP-5 is tucked back in the corner under the chassis side rail. With rig in CW mode flip to send and measure the level and the frequency at TP-5. It should be approx 300mv rms or approx 850mv P-P on a scope at 8830.70mhz.

I would measure the level first before you look at it with a Freq Counter as the counter may pull the level down. If you dont have a means to measure CA-2 Carrier level and frequency then at minimum measure CW terminal at CAR-2 Unit board to make sure you are getting CW TX bias voltage.

If you remove the 2 screws that secure the cover you will see a white 10 pin connector. The 3rd pin from the Crystal is the CW terminal. When you flip to send in CW mode should see approx 9.0vdc here. If you have 9vdc and still no output then suspect bad switching diode D1. D1 is close to the Crystal and you can measure the voltage at its anode and cathode. When you flip to send in CW mode should read approx 9vdc on the anode and approx 8.3vdc on the cathode. Note: The 9vdc will depend on where the AVR regulated 9vdc has been set too.

Ray

I forgot to mention where I am going with this (if not obvious) is a bad/dirty Mode switch contact or a broken wire at the mode switch in CW mode. The fact that you have output in FSK tells me that you do have approx 0.0 to 0.60vdc at TP-2 which then means the path from CV to the BM is good.

If you have no DMM, VOM, or VTVM the mode switch in a TS820 is an open deck type and pretty accessible with bottom cover off so you should be able to apply some deoxit and canned air to clean the contacts.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK well that would have been a quick fix and not first time so had to ask.

What test gear do you have and what is your comfort level to take measurements inside the rig?

When you inject audio into mic line and get output it tells you that your Balanced Modulator is working. In CW mode to produce output from the BM the Car Pot provides variable DC voltage to bias on the ring diodes. It is derives this bias voltage from regulated 9vdc from AVR board thru mode switch contacts.

The BM is on the IF board. Need to measure at Conn IF-5 at the CV terminal. Should see variable 0 to 9vdc at CV as you adjust the Car Pot thru its range.

Then measure at TP-2 and should see approx 0.0 to 0.70vdc as you adjust the Car Pot.

45485. RE: RE: TS-820 strange transmit problem

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-26 01:20:15 UTC
From: <wagstw46@...>
Topic: 45375 Message: 45485

It is easy to test CW filter switching diodes D7 and D8. I thought you already did this and reported good?

As previously noted my plug is in C all the way toward the front panel.

Conn IF-2 pins 4 and 5 have approx 12.9vdc on them in Rx and Tx for CW-R, CW-T, FSK-R, and FSK-T.

The cathode of D7 is:
CW-R and FSK-R = 2.90vdc
CW-T and FSK- T = 2.90vdc

The cathode of D8 is : (Note: When you connect voltmeter back ground noise will drop significantly).
CW-R and FSK-R = 10.0vdc
CW-T and FSK-T = 9.80vdc

The reading will be different as the diodes are biased to different current levels. You can see the difference in the supply resistors for each diode.

I have never been able to measure TX level diagram RF voltages accurately using a 1X scope probe. It will pull your ALC indication down from FSD (40 over) to approx 25 over.

You should be able to measure the 8.830mhz TIF signal level at the input and output of the CW Xtal filter. I thought we did this a long time ago?

It is normal for the filters to have an insertion loss. Should have a minimum of approx 25mv rms at D7 input and minimum of approx 19mv rms at D8 output.

Here are my RF level measurements at D7 and D8:

Test conditons: 14.175mhz, Heater on , SG switch off, CW mode, Drive control peaked, Car Pot at 2.5 (for full scale ALC deflection or 40 over)

Boonton 92E (using 10x scope probe very close to same levels)
D7 = 58mv
D8 = 25mv

You can jumper across your CW filter with a couple of mini-grabber test leads with a 0.047uf capacitor in series.

Could have good switching diodes and good filter but bad solder connections at the filter?

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I have made a discovery that will probably tell us where the actual problem is. I was googling how to replace CW filter and found this link:
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2

So I downloaded the operators manual and looked at page 34. Kenwood is perfectly clear about this. If the plug is in position A, the CW filter is bypassed.

I put the plug in position A and can tune to full power out in CW mode. If I place the plug in position B or C I get no power out when in CW mode.

Does this indicate a bad CW filter? The filter works fine in receive mode. The only thing I have noticed is that if I switch from USB to CW the signal drops 1 S-unit when peaked for max signal in both modes.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

At this point I am using my scope with 1 meg input. If is become suspicious of the reading I switch the 10X on and take the reading that way.

An immediate problem I see is I only have 10mV P-P at the drain of Q1 in FSK mode and 0 output in CW mode. The diagram says there should be 250 mV rms there. If I pull the CW filter out of the radio, how does the CW transmit work? Does the signal then go through the USB filter or do I need to install a jumper where the CW filter was?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Yes they are RMS.

I take them at around 14.175 to 14.200 mhz with the Car Level pot advanced to the point that with the Drive Control adjusted for a peak in ALC indication at panel meter full scale deflection. Then switch to CW mode and load to approx 100 watts out and turn off SG switch. Leave Car Level and Drive control alone.

Measured values will vary depending on what test instrument you are using, length of any test jumper leads used to access the test points, line voltage.

For example 8.830mhz TIF output at the IF board and input at the RF board is shown as 0.038v. This is 38.0 mv rms rf volts or 38 x 2.828 = 107 mv P-P. So if you have approx 100mv P-P TIF you are good.

Output of the TX Mixer is 1.4v rms or 4.0v P-P. This RF drive level is now 14.175 mhz.

If you plan on doing a lot of this work suggest you invest in a RF Millivolt meter. I use a Boonton 92E. I find it loads the circuits less and just easier and faster to use.

Of coures once you get to the 1.4 volts at output of the TX Mixer the old fashioned RF probe and VTVM works great. Just have to use multi-diode probe at plate of Driver tube and control grids of the Finals. I used a Heath 309C and PK-3 probes and a IM-18 VTVM for years

and still have them for fall back.

Are the transmit levels on page 42 of the service manual correct? Are those RMS values?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Thanks Terry. I have been talking to you since you have been helping. I don't know what made me put Dave on the last message (old age maybe).

I decided to start over from the beginning and go stage by stage this afternoon. This is what I did:
(All measurements taken with Send switch operated and Mode switch in CW position. Also, the measurements are the same in both CW and FSK modes.)

I suspected D1 or L1 was bad on the CAR-II board was bad but that is not the case. I have 720mV on CA2 leaving the CAR-II board in both CW and FSK send modes. I also have 720mV P-P on CA2 (IF5-13) on the IF board. I have 100mV P-P at the coax that connects to C92 on the IF board. On the other end of that coax where it connects to the top of T4 on the IF board I also have 100mV P-P. I would have thought the signal out of Q18 would have been stronger but maybe not.

I have 340mV at the junction of the cathode of D7 and C14 on the IF board. I have 280mV on the side of C14 where it feeds the CW filter. The signal going into the filter measures 8.830755 MHz. I only have 6mV P-P coming out of the crystal filter. Is the crystal filter used for transmit?

I connected the antenna to the radio and 20 meters is open. Tuning in CW signals in USB mode and switching to CW mode drops the signal by about 1 S-Unit when the signal is peaked for max signal in both modes.

Where do I go from here?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Are you talking Dave or Terry ? If someone is helping you off list I can back away as I have a pretty full plate right now.

I am not clear where you are measuring this 40mv P-P signal at?

Before I go I will mention that it is normal to not have a clean sine wave at TIF. It does have harmonic content and it is as you say due to LO mixing action. In this case it is coming from the VCO signal feeding back from the TX Mixer on RF board to the IF board.

This is easy to confirm with a TS-830 as you can easily unplug the VCO cable from the PLL board and the TIF signal will then be a nice clean 8.830mhz sine wave.

Dont worry about the complex waveform. Should still be able to get a reasonably close TIF measurement. It may not match exactly the levels on the TX Level Diagram,but you can compare it to the level you get with FSK carrier oscillator.

I dont use a O-scope to run TX Level diagrams once I get to the output of the TIF amp. I use a Boonton RF Millivolt meter and measure levels in rms and the "dirty" TIF signal presents no problem.

I have a new digital O-scope and it has a variety of digital filters. If I set it for a LP filter with a roll off frequency of 10mhz I can get a pretty clean 8.830 TIF sine wave display.

I dont know the Tek 2445 capability in this regard.

One final reminder is that good TIF signal level of approx 38mv rms or 107mv P-P is based on the premise that you accurately measured CA2 at the iF board of approx 300mv rms or 850mv P-P.

If that signal is not there then you would need to repeat the testing I asked you to do at the Carrier Osc board to confirm the 9vdc CW diode switching voltage is available at D1 and Q2 Buffer amp is being turned on.

I have been providing direction based on your reporting back that you have good CA-2 at Carrier board and good CA-2 at TP-5 on IF board.

If good Level at TP-5 then should have proper level at the wiper of VR-5 on the Balanced Mod. As we have discussed. No dc bias from CV and no Carrier at wiper of VR-5 then no output from the Bal Modulator.

I am pretty confident that you do have proper bias voltage from CCW to full CW on the Car Pot, but I am not certain yet that you have proper carrier output from the BM in CW mode.

Good luck.

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Dave,

I have VFO set to 14.175. With Car pot at 1200, in CW mode I get 40mV P-P in RX mode. When I flip the Send switch, the signal stays at 40 mV but it is no longer a sine wave. It is some kind of more or less sine wave with a lot of noise on it. With the Car pot at max, the noisy sinewave increases to 60 mV P-P in Send mode.

In FSK mode with Car at 1200 I get 250mV P-P in Send mode. With Car at Max I get 800 mV P-P in Send mode.

At Conn RF1-10 I get 140mV P-P in CW Send mode. I get 800mV P-P in FSK Send mode.

At the mixer output (Q1 and Q8 side of C8) I get 100 mV P-P in CW Send mode. I get 1V P-P in FSK Send mode. The signal at that point is not a sinewave but seems to have multiple signals. Probably some LO feedthrough on the mixer. The frequency counter agrees with the Kendwood readout as 14.1748 MHz.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Sorry about Q10 vs Q18. My fingers work better than what is left of my brain.

The 3 conductor plug should be positioned in forward position toward the front panel.

One thing we did not talk about is whereiyou should have the Car Level Pot set to take these measurements.

The TX Level Diagram is shown in the Service Manual. These levels were taken by Kenwood by loading the rig to approx 100 watts out at 14.175mhz and then turn the SG switch off and leave Car pot alone and Drive control alone.

Since you have no RF output in CW mode I suggest you do this for remainder of the readings:

1. VFO 14.175
2. Peak the Drive Control on receiver noise or the marker signal
3. Car Level Pot 1200
4. Heater on
5. SG switch off
6. Flip to Send to take RF drive levels

So the differences in voltages may be due to where we each have our Car Level pot set at.

Suggest you measure the voltage and frequency of the TIF signal at IF-3 Pin 2 one more time and it should be approx 250mv rms or 700mv P-P @ 8830.7mhz.

If you have close to this time to move on to the RF board. I must say this is getting a little odd as you have good output ini SSB and FSK which tells us you have good TIF level and the TX Mixer on RF Board is working which means you have good VCO (LO to the mixer).

Are you 100% certain you have no CW RF output on all bands? If so, then proceed on to the RF board with Heaters On and SG off and rig peaked as noted above.

You should have close to the values noted on the TX Level Diagram. At Conn RF-1 Pin 10 the 8.830 TIF signal level is approx 38mv rms or 108 P-P.

At output of TX Mixer should have approx 1.5v rms or 4.2v P-P rf drive at MD. At MD frequency will now be 14.175mhz transmit frequency.

If you have no RF drive or very weak at MD then need to measure the VCO level and frequency at RF-1 pin 4 and on board at TP-1. Should be close to 1.0v rms level. If no VCO try on other bands.

We are making good progress. Your Tek 2445 is perfect scope for KW Hybrid work and you apparently know how to use it and can read a schematic and can locate points on these high density boards to take measurements. This really helps.

Based on your report of no RF output in CW mode I would have thought we would have found no TIF sig at output of the IF board. TIF is not band specific and often is caused by no output from the Bal Modulator, This is why I had you start by testing for bias voltage and LO signal available. Never expected that we would be at the RF board and TX Mixer based on good RF output on other modes.

Terry,

I read a little over 700mV at the drain of Q18 (actually the backside of C92 feeding the coax). I think you meant Q18 instead of Q10.

D7 and D8 are the CW switching diodes. With the mode switch in CW position, I have 2.98 volts on the anode of D7 and 2.34 volts on the cathode. I have 10.0 volts on the anode of D8 and 9.40 volts on the cathode. These voltages are there in both RX and TX, just a few 10ths of a volt lower in TX mode.

Can you confirm how the 3 pin cable ofr IF2 is supposed to plug in? It only has 3 wires but there are 5 pins on the IF board at that point. According to the chassis wiring diagram, only the first 3 pins are used as they come from S6-1.

I don't think there is anything wrong with the CW filter and the switching diodes as the CW filter works fine in RX mode.

I have 400mV P-P on Gate 1 of Q1 instead of the 160mV when flipping Send. I also have 2400mV P-P on the drain instead of 1000mV when flipping Send.

TIF signal on Conn IF-3 is 400mV P-P and the sine wave isn't quiet as clean there as it is on the drain of Q1.

Hopefully we are making progress.

Ray:

Good job. Much better.

If I understand your chart you are telling me that you have approx 640mv P-P @ 8.83077 at TP-5 in CW mode with rig flipped to Send (heaters off and SG switch off). 900mv P-P is attainable by adjusting T1 on CAR-2 board, but can do later unless you want to peak it now. 640mv will work for testing.

If this is true then you have confirmed that you have the two things you need at the Balanced Mod to produce RF output from it in CW mode. 1. Offset bias voltage and 2. Proper Carrier freq and level.

From the BM output the CW signal is routed to the Crystal IF Filter and then to Q1 the Transmit IF Amp or TIF amp. TIF signal leaves the IF board and is routed to the RF board to the TX Mixer where it is mixed with VCO to produce the actual transmit rf drive signal. No TIF signal and there will be no RF drive and no RF output. Also no VCO or low VCO level and no rf drive. Lets validate that we have TIF signal in CW mode first.

Unfortunately KW didnt provide a nice test point at the output of the Balanced Mod to measure the DSBSC signal in SSB mode or the Carrier in CW mode. However, you can get on the Drain of Q10 with a hat pin or floral arrangement pin and mini-grabber test lead. If you

locate the BM ring diodes D26-D29 and then output Xfmr T10 you will see Q10. It is a metal can dual gate mosfet. Looking down on the can the Drain is the upper right lead. You should read approx 800mv P-P here. This signal is routed to the Xtal filter thru switcing diodes.

Do you have the CW filter installed. It is rare but could have a bad filter. More common to have a bad switching diode.

After signal passes thru the Xtal filter it is applied to Gate 1 of TIF amp Q1. It is also a metal can dual gate mosfet and sits outside and almost between the two filters at the inboard end. Looking down on Q1 Gate 1 is at 1200. Should have approx 160mv P-P here. The Drain is at 0600 and should have approx 1000mv P-P. TIF output is on Conn IF-3 Pin 2 and should have approx 850mv P-P here. You can jump right to measuring TIF output if you want and if good then off to the RF board.

We know that you have TIF output in FSK mode as you reported good RF output in that mode. I dont kow if you keyed rig in FSK and noted the 170hz shift or not, but not important right now. Also, you should have noted that the RF output in FSK is lower as the 820 lowers the Finals Screen Grid voltage in FSK mode so the tubes plate dissipation is not exceeded in this high duty cycle mode.

That should be enough for now.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

This is what I am seeing:
TP-5 and CJ3-CA2 have the same levels in CW and FSK modes: 820mV P-P in RX mode. Flipping Send switch the level drops to 640mV P-P. I have a Tektronix 2445 Scope and have the probe in 10X to prevent loading the circuit.

Frequencies measured at CJ3-CA2:
RX mode FSK - 8.828414 - TX mode FSK 8.830620
RX mode LSB - 8.828414 - TX mode LSB 8.828579
RX mode USB - 8.831460 - TX mode USB 8.831625
RX mode CW - 8.831460 - TX mode CW 8.830777

Frequencies measured at TP-5:
RX mode FSK - 8.828410 - TX mode FSK 8.830616
RX mode LSB - 8.828410 - TX mode LSB 8.828575
RX mode USB - 8.831450 - TX mode USB 8.831622
RX mode CW - 8.831446 - TX mode CW 8.830773

I am using a Simpson 710 Frequency counter. Specs say 1 Meg input shunted by 30 pF. The slight differences in frequency readings between CJ3-CA2 and TP-5 is probably due to the cable capacitance of the cable between IF5-13 and CJ3-CA2.

I have been taking all of these measurements with the SG switch turned off and the heater switch turned off.

Ray:

I mis-spoke in Item 2 when I said you cant measure carrier at TP-5 in Rx in any of the mode switch positions. There will be legitimate carrier but not of interest.

There will be Carrier at CA-2 and TP-5 in Rx in all positions of the mode switch that you should see, but it is meaningless for CW Tx operation. It was not correct for me to label it as "Leakage" signals.

It is there by design but not for Rx or Tx operation. CA-1 Carrier Osc signals are coupled to the CAR-2 board to amp Q3 and then on to TP-5 at IF board and then sampled and sent to the CCR lead to provide carrier oscillator signals for the Counter Mixer Board. So the carrier osc signals you were measuring at each position of the mode switch in Rx are there by design to feed the counter, but of no interest to us as not utilized for the BM and CW transmit.

So you will see approx 250mv rms at 8831.50 mhz in CW and LSB and 250mv at 8828.5mhz in LSB and FSK, but not used by the BM. BM is not used in Rx operation. So disregard these signal other than the low levels you measured cannot be correct if your counter is working properly. I suspect you are not using O-scope properly. Are you using a 10X probe?

What I meant to say is at CA-2 and TP-5 the only frequency and level we care about is in CW and FSK positions of the mode switch in Tx. CA-2 carrier oscillator should be approx 250mv rms @ 8830.70mhz when in CW and FSK mode when flipped to send. This is what you are trying to validate. Measure at TP-5 in FSK as you know it is working. So use it to get your O-scope set up correctly and you can see approx 850mv P-P at 8830.7mhz. Once you can read that on your O-scope now switch to CW mode and flip to send to measure carrier osc signal level at TP-5.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Yes this new format gives me problems as well.

1. You are getting proper dc bias voltage to the BM. You need to confirm you are getting the Carrier Osc signal.

2. You cannot measure any Carrier freq or level at TP-5 in RX for any position of the mode switch. You may read some leakage signals in RX mode but meaningless. The BM is only used for TX and not RX. Only time you can measure any meaningful Carrier Osc frequency or level at TP-5 is in TX with the mode switch in CW or FSK. Carrier in RX mode is applied to another Mixer called the Product Detector and it arrives at IF board on IF-4 C1A terminal. You have separate Carrier Oscillators for RX and TX.

Also, the Car Level Pot has nothing to do with the Carrier Osc levels produced on the CAR Assembly Unit. The Car level pot unbalances the balanced modulator and determines the carrier output level from the BM.

You really need to measure CA-2 produced on the CAR-2 board. If you do not have 300mv of 8830.7mhz at TP-5 in CW mode when you flip to Send then you have to work your way back from TP-5 to CAR-2 board. CA2 can be checked on the 7th terminal up on the white terminal block on the CAR-2 board. On the IF board it comes in on Conn IF-5 pin 13.

At this point you have not confirmed that you have CAR-2 Q1 Oscillator running and available.

3. The DC voltages that you measured at D1 prove that you are getting the turn on voltages for Buffer amp Q2 so if Q1 is oscillating should get CW TX Carrier at CJ-3 and on to the IF board if all connectors are good.

You may have to adjust the frequency and output level but can talk about that later.

Suggest you buy a Freq Counter. Can measure Freq roughly with O-scope. Some measure and display Freq (may or may not do so accurately) and some require using F=1/T and not accurate enough for adjusting the Oscillators in the KW hybrids.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Let's try this again. For some reason yahoo has been mangling my posts. This has been a problem ever since they went to this new stupid format they are using.

Measuring at TP-2 the voltage varies from 16 mV to .443V when adjusting the CAR control in both FSK and CW mode. On Conn IF-5 at the CV terminal, the voltage varies from .12V to 8.95V in both FSK and CW mode when adjusting the CAR control.

Also, on the FIX VOX board FIX3-11 is grounded with no key plugged in. Plugging a key in, FIX3-11 follows the key (open key up, grounded key down).

I have cleaned the contacts on the Mode switch and checked for broken wires.

At TP-5 I measure 8.831434 MHz at .64V P-P (on scope) in all positions of the mode switch without the Send switch flipped. When I flip the Send switch the voltage drops to .48V P-P. The CAR control has no affect on the signal level with the Send switch in either position.

I measure 8.97V at the CW terminal on CAR-2 when I flip the Send switch. I measure 8.94V at the anode of D1 and 8.19V at the cathode when the Send switch is flipped.

I have a couple of multimeters, a 150 MHz analog scope, 100 MHz digital scope, W7ZOI power meter, and a KA7EXM power meter. I feel comfortable taking measurements anywhere inside the radio including the Final Cage.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

For some reason I cannot read your entire response? It appears you are reporting back that you have good bias voltage available at the BM from the Car Pot. In CW TX mode you need this bias voltage and you need the local oscillator (LO) or Carrier to produce an output. Which in this case it is 8.830.70mhz CA-2 produced on the CAR-2 Unit.

You are getting CA-2 Carrier in FSK mode so it tells me the Crystal and the soldering at its pins have to be good.

If you have a RF millivolt meter or O-scope you can measure the 8830.7 mhz Carrier at the IF board at TP-5.TP-5 is tucked back in the corner under the chassis side rail. With rig in CW mode flip to send and measure the level and the frequency at TP-5. It should be approx 300mv rms or approx 850mv P-P on a scope at 8830.70mhz.

I would measure the level first before you look at it with a Freq Counter as the counter may pull the level down. If you dont have a means to measure CA-2 Carrier level and frequency then at minimum measure CW terminal at CAR-2 Unit board to make sure you are getting CW TX bias voltage.

If you remove the 2 screws that secure the cover you will see a white 10 pin connector. The 3rd pin from the Crystal is the CW terminal. When you flip to send in CW mode should see approx 9.0vdc here. If you have 9vdc and still no output then suspect bad switching diode D1. D1 is close to the Crystal and you can measure the voltage at its anode and cathode. When you flip to send in CW mode should read approx 9vdc on the anode and approx 8.3vdc on the cathode. Note: The 9vdc will depend on where the AVR regulated 9vdc has been set too.

Ray

I forgot to mention where I am going with this (if not obvious) is a bad/dirty Mode switch contact or a broken wire at the mode switch in CW mode. The fact that you have output in FSK tells me that you do have approx 0.0 to 0.60vdc at TP-2 which then means the path from CV to the BM is good.

If you have no DMM, VOM, or VTVM the mode switch in a TS820 is an open deck type and pretty accessible with bottom cover off so you should be able to apply some deoxit and canned air to clean the contacts.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK well that would have been a quick fix and not first time so had to ask.

What test gear do you have and what is your comfort level to take measurements inside the rig?

When you inject audio into mic line and get output it tells you that your Balanced Modulator is working. In CW mode to produce output from the BM the Car Pot provides variable DC voltage to bias on the ring diodes. It is derives this bias voltage from

regulated 9vdc from AVR board thru mode switch contacts.

The BM is on the IF board. Need to measure at Conn IF-5 at the CV terminal. Should see variable 0 to 9vdc at CV as you adjust the Car Pot thru its range.

Then measure at TP-2 and should see approx 0.0 to 0.70vdc as you adjust the Car Pot.

From: <rcbuckiii@...>
Topic: 45375 Message: 45486

Terry,

My voltages at D7 and D8 are virtually identical to yours. I had previously measured the levels at D7 and D8. I measured 280mV P-P where C14 connects to the CW filter and only 6mV P-P out of the filter. But that was before I changed the cable to position A. I will have to move the cable back to C and re-measure tomorrow. I will also pull the IF board out and resolder the CW crystal filter connections. It may be bad solder connections as you suggest.

I just made my first contact in 17 years on 7.020 with W5TZC about 30 mins ago. He gave me a 579 which is pretty good considering my antenna is only 8 feet off the ground. I also still have to address why they final isn't tuning properly on 40 meters. It tuned max power with plate knob pointer sitting on the 5 of 3.5. It dips at 14 on 20 meters.

If I can get the CW filter issue worked out I will go through a complete tuneup of the radio following the service manual procedures.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

It is easy to test CW filter switching diodes D7 and D8. I thought you already did this and reported good?

As previously noted my plug is in C all the way toward the front panel.

Conn IF-2 pins 4 and 5 have approx 12.9vdc on them in Rx and Tx for CW-R, CW-T, FSK-R, and FSK-T.

The cathode of D7 is:
CW-R and FSK-R = 2.90vdc
CW-T and FSK- T = 2.90vdc

The cathode of D8 is : (Note: When you connect voltmeter back ground noise will drop significantly).
CW-R and FSK-R = 10.0vdc
CW-T and FSK-T = 9.80vdc

The reading will be different as the diodes are biased to different current levels. You can see the difference in the supply resistors for each diode.

I have never been able to measure TX level diagram RF voltages accurately using a 1X scope probe. It will pull your ALC indication down from FSD (40 over) to approx 25 over.

You should be able to measure the 8.830mhz TIF signal level at the input and output of the CW Xtal filter. I thought we did this a long time ago?

It is normal for the filters to have an insertion loss. Should have a minimum of approx 25mv rms at D7 input and minimum of approx 19mv rms at D8 output.

Here are my RF level measurements at D7 and D8:

Test conditons: 14.175mhz, Heater on , SG switch off, CW mode, Drive control peaked, Car Pot at 2.5 (for full scale ALC deflection or 40 over)

Boonton 92E (using 10x scope probe very close to same levels)
D7 = 58mv
D8 = 25mv

You can jumper across your CW filter with a couple of mini-grabber test leads with a 0.047uf capacitor in series.

Could have good switching diodes and good filter but bad solder connections at the filter?

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I have made a discovery that will probably tell us where the actual problem is. I was googling how to replace CW filter and found this link:
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2

So I downloaded the operators manual and looked at page 34. Kenwood is perfectly clear about this. If the plug is in position A, the CW filter is bypassed.

I put the plug in position A and can tune to full power out in CW mode. If I place the plug in position B or C I get no power out when in CW mode.

Does this indicate a bad CW filter? The filter works fine in receive mode. The only thing I have noticed is that if I switch from USB to CW the signal drops 1 S-unit when peaked for max signal in both modes.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

At this point I am using my scope with 1 meg input. If is become suspicious of the reading I switch the 10X on and take the reading that way.

An immediate problem I see is I only have 10mV P-P at the drain of Q1 in FSK mode and 0 output in CW mode. The diagram says there should be 250 mV rms there. If I pull the CW filter out of the radio, how does the CW transmit work? Does the signal then go through the USB filter or do I need to install a jumper where the CW filter was?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Yes they are RMS.

I take them at around 14.175 to 14.200 mhz with the Car Level pot advanced to the point that with the Drive Control adjusted for a peak in ALC indication at panel meter full scale deflection. Then switch to CW mode and load to approx 100 watts out and turn off SG switch. Leave Car Level and Drive control alone.

Measured values will vary depending on what test instrument you are using, length of any test jumper leads used to access the test points, line voltage.

For example 8.830mhz TIF output at the IF board and input at the RF board is shown as 0.038v. This is 38.0 mv rms rf volts or 38 x 2.828 = 107 mv P-P. So if you have approx 100mv P-P TIF you are good.

Output of the TX Mixer is 1.4v rms or 4.0v P-P. This RF drive level is now 14.175 mhz.

If you plan on doing a lot of this work suggest you invest in a RF Millivolt meter. I use a Boonton 92E. I find it loads the circuits less and just easier and faster to use.

Of coures once you get to the 1.4 volts at output of the TX Mixer the old fashioned RF probe and VTVM works great. Just have to use multi-diode probe at plate of Driver tube and control grids of the Finals. I used a Heath 309C and PK-3 probes and a IM-18 VTVM for years and still have them for fall back.

Terry,

Are the transmit levels on page 42 of the service manual correct? Are those RMS values?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Thanks Terry. I have been talking to you since you have been helping. I don't know what made me put Dave on the last message (old age maybe).

I decided to start over from the beginning and go stage by stage this afternoon. This is what I did:
(All measurements taken with Send switch operated and Mode switch in CW position. Also, the measurements are the same in both CW and FSK modes.)

I suspected D1 or L1 was bad on the CAR-II board was bad but that is not the case. I have 720mV on CA2 leaving the CAR-II board in both CW and FSK send modes. I also have 720mV P-P on CA2 (IF5-13) on the IF board. I have 100mV P-P at the coax that connects to C92 on the IF board. On the other end of that coax where it connects to the top of T4 on the IF board I also have 100mV P-P. I would have thought the signal out of Q18 would have been stronger but maybe not.

I have 340mV at the junction of the cathode of D7 and C14 on the IF board. I have 280mV on the side of C14 where it feeds the CW filter. The signal going into the filter measures 8.830755 MHz. I only have 6mV P-P coming out of the crystal filter. Is the crystal filter used for transmit?

I connected the antenna to the radio and 20 meters is open. Tuning in CW signals in USB mode and switching to CW mode drops the signal by about 1 S-Unit when the signal is peaked for max signal in both modes.

Where do I go from here?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Are you talking Dave or Terry ? If someone is helping you off list I can back away as I have a pretty full plate right now.

I am not clear where you are measuring this 40mv P-P signal at?

Before I go I will mention that it is normal to not have a clean sine wave at TIF. It does have harmonic content and it is as you say due to LO mixing action. In this case it is coming from the VCO signal feeding back from the TX Mixer on RF board to the IF board.

This is easy to confirm with a TS-830 as you can easily unplug the VCO cable from the PLL board and the TIF signal will then be a nice clean 8.830mhz sine wave.

Dont worry about the complex waveform. Should still be able to get a reasonably close TIF measurement. It may not match exactly the levels on the TX Level Diagram,but you can compare it to the level you get with FSK carrier oscillator.

I dont use a O-scope to run TX Level diagrams once I get to the output of the TIF amp. I use a Boonton RF Millivolt meter and measure levels in rms and the "dirty" TIF signal presents no problem.

I have a new digital O-scope and it has a variety of digital filters. If I set it for a LP filter with a roll off frequency of 10mhz I can get a pretty clean 8.830 TIF sine wave display.

I dont know the Tek 2445 capability in this regard.

One final reminder is that good TIF signal level of approx 38mv rms or 107mv P-P is based on the premise that you accurately measured CA2 at the iF board of approx 300mv rms or 850mv P-P.

If that signal is not there then you would need to repeat the testing I asked you to do at the Carrier Osc board to confirm the 9vdc CW diode switching voltage is available at D1 and Q2 Buffer amp is being turned on.

I have been providing direction based on your reporting back that you have good CA-2 at Carrier board and good CA-2 at TP-5 on IF board.

If good Level at TP-5 then should have proper level at the wiper of VR-5 on the Balanced Mod. As we have discussed. No dc bias from CV and no Carrier at wiper of VR-5 then no output from the Bal Modulator.

I am pretty confident that you do have proper bias voltage from CCW to full CW on the Car Pot, but I am not certain yet that you have proper carrier output from the BM in CW mode.

Good luck.

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Dave,

I have VFO set to 14.175. With Car pot at 1200, in CW mode I get 40mV P-P in RX mode. When I flip the Send switch, the signal stays at 40 mV but it is no longer a sine wave. It is some kind of more or less sine wave with a lot of noise on it. With the Car pot at max, the noisy sinewave increases to 60 mV P-P in Send mode.

In FSK mode with Car at 1200 I get 250mV P-P in Send mode. With Car at Max I get 800 mV P-P in Send mode.

At Conn RF1-10 I get 140mV P-P in CW Send mode. I get 800mV P-P in FSK Send mode.

At the mixer output (Q1 and Q8 side of C8) I get 100 mV P-P in CW Send mode. I get 1V P-P in FSK Send mode. The signal at that point is not a sinewave but seems to have multiple signals. Probably some LO feedthrough on the mixer. The frequency counter agrees with the Kendwood readout as 14.1748 MHz.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Sorry about Q10 vs Q18. My fingers work better than what is left of my brain.

The 3 conductor plug should be positioned in forward position toward the front panel.

One thing we did not talk about is whereiyou should have the Car Level Pot set to take these measurements.

The TX Level Diagram is shown in the Service Manual. These levels were taken by Kenwood by loading the rig to approx 100 watts out at 14.175mhz and then turn the SG switch off and leave Car pot alone and Drive control alone.

Since you have no RF output in CW mode I suggest you do this for remainder of the readings:

1. VFO 14.175
2. Peak the Drive Control on receiver noise or the marker signal
3. Car Level Pot 1200
4. Heater on
5. SG switch off
6. Flip to Send to take RF drive levels

So the differences in voltages may be due to where we each have our Car Level pot set at.

Suggest you measure the voltage and frequency of the TIF signal at IF-3 Pin 2 one more time and it should be approx 250mv rms or 700mv P-P @ 8830.7mhz.

If you have close to this time to move on to the RF board. I must say this is getting a little odd as you have good output ini SSB and FSK which tells us you have good TIF level and the TX Mixer on RF Board is working which means you have good VCO (LO to the mixer).

Are you 100% certain you have no CW RF output on all bands? If so, then proceed on to the RF board with Heaters On and SG off and rig peaked as noted above.

You should have close to the values noted on the TX Level Diagram. At Conn RF-1 Pin 10 the 8.830 TIF signal level is approx 38mv rms or 108 P-P.

At output of TX Mixer should have approx 1.5v rms or 4.2v P-P rf drive at MD. At MD frequency will now be 14.175mhz transmit frequency.

If you have no RF drive or very weak at MD then need to measure the VCO level and frequency at RF-1 pin 4 and on board at TP-1. Should be close to 1.0v rms level. If no VCO try on other bands.

We are making good progress. Your Tek 2445 is perfect scope for KW Hybrid work and you apparently know how to use it and can read a schematic and can locate points on these high density boards to take measurements. This really helps.

Based on your report of no RF output in CW mode I would have thought we would have found no TIF sig at output of the IF board. TIF is not band specific and often is caused by no output from the Bal Modulator, This is why I had you start by testing for bias voltage and LO signal available. Never expected that we would be at the RF board and TX Mixer based on good RF output on other modes.

Terry,

I read a little over 700mV at the drain of Q18 (actually the backside of C92 feeding the coax). I think you meant Q18 instead of Q10.

D7 and D8 are the CW switching diodes. With the mode switch in CW position, I have 2.98 volts on the anode of D7 and 2.34 volts on the cathode. I have 10.0 volts on the anode of D8 and 9.40 volts on the cathode. These voltages are there in both RX and TX, just a few 10ths of a volt lower in TX mode.

Can you confirm how the 3 pin cable ofr IF2 is supposed to plug in? It only has 3 wires but there are 5 pins on the IF board at that point. According to the chassis wiring diagram, only the first 3 pins are used as they come from S6-1.

I don't think there is anything wrong with the CW filter and the switching diodes as the CW filter works fine in RX mode.

I have 400mV P-P on Gate 1 of Q1 instead of the 160mV when flipping Send. I also have 2400mV P-P on the drain instead of 1000mV when flipping Send.

TIF signal on Conn IF-3 is 400mV P-P and the sine wave isn't quiet as clean there as it is on the drain of Q1.

Hopefully we are making progress.

Ray:

Good job. Much better.

If I understand your chart you are telling me that you have approx 640mv P-P @ 8.83077 at TP-5 in CW mode with rig flipped to Send (heaters off and SG switch off). 900mv P-P is attainable by adjusting T1 on CAR-2 board, but can do later unless you want to peak it now. 640mv will work for testing.

If this is true then you have confirmed that you have the two things you need at the Balanced Mod to produce RF output from it in CW mode. 1. Offset bias voltage and 2. Proper Carrier freq and level.

From the BM output the CW signal is routed to the Crystal IF Filter and then to Q1 the Transmit IF Amp or TIF amp. TIF signal leaves the IF board and is routed to the RF board to the TX Mixer where it is mixed with VCO to produce the actual transmit rf drive signal. No TIF signal and there will be no RF drive and no RF output. Also no VCO or low VCO level and no rf drive. Lets validate that we have TIF signal in CW mode first.

Unfortunately KW didnt provide a nice test point at the output of the Balanced Mod to measure the DSBSC signal in SSB mode or the Carrier in CW mode. However, you can get on the Drain of Q10 with a hat pin or floral arrangement pin and mini-grabber test lead. If you locate the BM ring diodes D26-D29 and then output Xfmr T10 you will see Q10. It is a metal can dual gate mosfet. Looking down on the can the Drain is the upper right lead. You should read approx 800mv P-P here. This signal is routed to the Xtal filter thru switcing diodes.

Do you have the CW filter installed. It is rare but could have a bad filter. More common to have a bad switching diode.

After signal passes thru the Xtal filter it is applied to Gate 1 of TIF amp Q1. It is also a metal can dual gate mosfet and sits outside and almost between the two filters at the inboard end. Looking down on Q1 Gate 1 is at 1200. Should have approx 160mv P-P here. The Drain is at 0600 and should have approx 1000mv P-P. TIF output is on Conn IF-3 Pin 2 and should have approx 850mv P-P here. You can jump right to measuring TIF output if you want and if good then off to the RF board.

We know that you have TIF output in FSK mode as you reported good RF output in that mode. I dont kow if you keyed rig in FSK and noted the 170hz shift or not, but not important right now. Also, you should have noted that the RF output in FSK is lower as the 820 lowers the Finals Screen Grid voltage in FSK mode so the tubes plate dissipation is not exceeded in this high duty cycle mode.

That should be enough for now.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

This is what I am seeing:
TP-5 and CJ3-CA2 have the same levels in CW and FSK modes: 820mV P-P in RX mode. Flipping Send switch the level drops to 640mV P-P. I have a Tektronix 2445 Scope and have the probe in 10X to prevent loading the circuit.

Frequencies measured at CJ3-CA2:
RX mode FSK - 8.828414 - TX mode FSK 8.830620
RX mode LSB - 8.828414 - TX mode LSB 8.828579
RX mode USB - 8.831460 - TX mode USB 8.831625
RX mode CW - 8.831460 - TX mode CW 8.830777

Frequencies measured at TP-5:
RX mode FSK - 8.828410 - TX mode FSK 8.830616
RX mode LSB - 8.828410 - TX mode LSB 8.828575
RX mode USB - 8.831450 - TX mode USB 8.831622
RX mode CW - 8.831446 - TX mode CW 8.830773

I am using a Simpson 710 Frequency counter. Specs say 1 Meg input shunted by 30 pF. The slight differences in frequency readings between CJ3-CA2 and TP-5 is probably due to the cable capacitance of the cable between IF5-13 and CJ3-CA2.

I have been taking all of these measurements with the SG switch turned off and the heater switch turned off.

Ray:

I mis-spoke in Item 2 when I said you cant measure carrier at TP-5 in Rx in any of the mode switch positions. There will be legitimate carrier but not of interest.

There will be Carrier at CA-2 and TP-5 in Rx in all positions of the mode switch that you should see, but it is meaningless for CW Tx operation. It was not correct for me to label it as "Leakage" signals.

It is there by design but not for Rx or Tx operation. CA-1 Carrier Osc signals are coupled to the CAR-2 board to amp Q3 and then on to TP-5 at IF board and then sampled and sent to the CCR lead to provide carrier oscillator signals for the Counter Mixer Board. So the carrier osc signals you were measuring at each position of the mode switch in Rx are there by design to feed the counter, but of no interest to us as not utilized for the BM and CW transmit.

So you will see approx 250mv rms at 8831.50 mhz in CW and LSB and 250mv at 8828.5mhz in LSB and FSK, but not used by the BM. BM is not used in Rx operation. So disregard these signal other than the low levels you measured cannot be correct if your counter is working properly. I suspect you are not using O-scope properly. Are you using a 10X probe?

What I meant to say is at CA-2 and TP-5 the only frequency and level we care about is in CW and FSK positions of the mode switch in Tx. CA-2 carrier oscillator should be approx 250mv rms @ 8830.70mhz when in CW and FSK mode when flipped to send. This is what you are trying to validate. Measure at TP-5 in FSK as you know it is working. So use it to get your O-scope set up correctly and you can see approx 850mv P-P at 8830.7mhz. Once you can read that on your O-scope now switch to CW mode and flip to send to measure carrier osc signal level at TP-5.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Yes this new format gives me problems as well.

1. You are getting proper dc bias voltage to the BM. You need to confirm you are getting the Carrier Osc signal.

2. You cannot measure any Carrier freq or level at TP-5 in RX for any position of the mode switch. You may read some leakage signals in RX mode but meaningless. The BM is only used for TX and not RX. Only time you can measure any meaningful Carrier Osc frequency or level at TP-5 is in TX with the mode switch in CW or FSK. Carrier in RX mode is applied to another Mixer called the Product Detector and it arrives at IF board on IF-4 C1A terminal. You have separate Carrier Oscillators for RX and TX.

Also, the Car Level Pot has nothing to do with the Carrier Osc levels produced on the CAR Assembly Unit. The Car level pot unbalances the balanced modulator and determines the carrier output level from the BM.

You really need to measure CA-2 produced on the CAR-2 board. If you do not have 300mv of 8830.7mhz at TP-5 in CW mode when you flip to Send then you have to work your way back from TP-5 to CAR-2 board. CA2 can be checked on the 7th terminal up on the white terminal block on the CAR-2 board. On the IF board it comes in on Conn IF-5 pin 13.

At this point you have not confirmed that you have CAR-2 Q1 Oscillator running and available.

3. The DC voltages that you measured at D1 prove that you are getting the turn on voltages for Buffer amp Q2 so if Q1 is oscillating should get CW TX Carrier at CJ-3 and on to the IF board if all connectors are good.

You may have to adjust the frequency and output level but can talk about that later.

Suggest you buy a Freq Counter. Can measure Freq roughly with O-scope. Some measure and display Freq (may or may not do so accurately) and some require using F=1/T and not accurate enough for adjusting the Oscillators in the KW hybrids.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Let's try this again. For some reason yahoo has been mangling my posts. This has been a problem ever since they went to this new stupid format they are using.

Measuring at TP-2 the voltage varies from 16 mV to .443V when adjusting the CAR control in both FSK and CW mode. On Conn IF-5 at the CV terminal, the voltage varies from .12V to 8.95V in both FSK and CW mode when adjusting the CAR control.

Also, on the FIX VOX board FIX3-11 is grounded with no key plugged in. Plugging a key in, FIX3-11 follows the key (open key up, grounded key down).

I have cleaned the contacts on the Mode switch and checked for broken wires.

At TP-5 I measure 8.831434 MHz at .64V P-P (on scope) in all positions of the mode switch without the Send switch flipped. When I flip the Send switch the voltage drops to .48V P-P. The CAR control has no affect on the signal level with the Send switch in either position.

I measure 8.97V at the CW terminal on CAR-2 when I flip the Send switch. I measure 8.94V at the anode of D1 and 8.19V at the cathode when the Send switch is flipped.

I have a couple of multimeters, a 150 MHz analog scope, 100 MHz digital scope, W7ZOI power meter, and a KA7EXM power meter. I feel comfortable taking measurements anywhere inside the radio including the Final Cage.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

For some reason I cannot read your entire response? It appears you are reporting back that you have good bias voltage available at the BM from the Car Pot. In CW TX mode you need this bias voltage and you need the local oscillator (LO) or Carrier to produce an output. Which in this case it is 8.830.70mhz CA-2 produced on the CAR-2 Unit.

You are getting CA-2 Carrier in FSK mode so it tells me the Crystal and the soldering at its pins have to be good.

If you have a RF millivolt meter or O-scope you can measure the 8830.7 mhz Carrier at the IF board at TP-5.TP-5 is tucked back in the corner under the chassis side rail. With rig in CW mode flip to send and measure the level and the frequency at TP-5. It should be approx 300mv rms or approx 850mv P-P on a scope at 8830.70mhz.

I would measure the level first before you look at it with a Freq Counter as the counter may pull the level down. If you dont have a means to measure CA-2 Carrier level and frequency then at minimum measure CW terminal at CAR-2 Unit board to make sure you are getting CW TX bias voltage.

If you remove the 2 screws that secure the cover you will see a white 10 pin connector. The 3rd pin from the Crystal is the CW terminal. When you flip to send in CW mode should see approx 9.0vdc here. If you have 9vdc and still no output then suspect bad switching diode D1. D1 is close to the Crystal and you can measure the voltage at its anode and cathode. When you flip to send in CW mode should read approx 9vdc on the anode and approx 8.3vdc on the cathode. Note: The 9vdc will depend on where the AVR regulated 9vdc has been set too.

I would check the voltage of the coils in the VCO(voltage controlled oscillator) Unit first. It's on the underside of the rig. Procedure is on Pg 52, Section 5-2 of the service manual. You will need a fine ended tuning tool and a decent voltmeter/vtvm at a minimum. I think that this should take care of the problem. Take your time...those coils can be a bit touchy

For some good initial(basic) troubleshooting, the 820(S) service manual has a "troubleshooting" section. Look on Pg's 38 - 41.

  Good Luck.

OK I forgot to give you the Anode voltages of D7 and D8 but you can just subtract approx 0.65vdc for the turn on voltage.

280mv P-P is high by my measurements, but if you read close to same in FSK-T then call it good. Certainly better than be too low.

6 mv P-P at output in CW-T is definitely a problem. As I said you can jumper the filter with a .047uf cap and see if you get CW Tx.

Is this the factory YG-88C filter?

I believe it has center frequency of 8830.7 mhz.and bandwidth of 500hz at -6dB.
I have never swept one.

It would not seem likely that you would have bad solder connections if the filter is working in FSK mode. Are you 100% certain you are not using the SSB filter in FSK mode?

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

My voltages at D7 and D8 are virtually identical to yours. I had previously measured the levels at D7 and D8. I measured 280mV P-P where C14 connects to the CW filter and only 6mV P-P out of the filter. But that was before I changed the cable to position A. I will have to move the cable back to C and re-measure tomorrow. I will also pull the IF board out and resolder the CW crystal filter connections. It may be bad solder connections as you suggest.

I just made my first contact in 17 years on 7.020 with W5TZC about 30 mins ago. He gave me a 579 which is pretty good considering my antenna is only 8 feet off the ground. I also still have to address why they final isn't tuning properly on 40 meters. It tuned max power with plate knob pointer sitting on the 5 of 3.5. It dips at 14 on 20 meters.

If I can get the CW filter issue worked out I will go through a complete tuneup of the radio following the service manual procedures.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

It is easy to test CW filter switching diodes D7 and D8. I thought you already did this and reported good?

As previously noted my plug is in C all the way toward the front panel.

Conn IF-2 pins 4 and 5 have approx 12.9vdc on them in Rx and Tx for CW-R, CW-T, FSK-R, and FSK-T.

The cathode of D7 is:
CW-R and FSK-R = 2.90vdc
CW-T and FSK- T = 2.90vdc

The cathode of D8 is : (Note: When you connect voltmeter back ground noise will drop significantly).
CW-R and FSK-R = 10.0vdc
CW-T and FSK-T = 9.80vdc

The reading will be different as the diodes are biased to different current levels. You can see the difference in the supply resistors for each diode.

I have never been able to measure TX level diagram RF voltages accurately using a 1X scope probe. It will pull your ALC indication down from FSD (40 over) to approx 25 over.

You should be able to measure the 8.830mhz TIF signal level at the input and output of the CW Xtal filter. I thought we did this a long time ago?

It is normal for the filters to have an insertion loss. Should have a minimum of approx 25mv rms at D7 input and minimum of approx 19mv rms at D8 output.

Here are my RF level measurements at D7 and D8:

Test conditons: 14.175mhz, Heater on , SG switch off, CW mode, Drive control peaked, Car Pot at 2.5 (for full scale ALC deflection or 40 over)

Boonton 92E (using 10x scope probe very close to same levels)
D7 = 58mv
D8 = 25mv

You can jumper across your CW filter with a couple of mini-grabber test leads with a 0.047uf capacitor in series.

Could have good switching diodes and good filter but bad solder connections at the filter?

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I have made a discovery that will probably tell us where the actual problem is. I was googling how to replace CW filter and found this link:
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2

So I downloaded the operators manual and looked at page 34. Kenwood is perfectly clear about this. If the plug is in position A, the CW filter is bypassed.

I put the plug in position A and can tune to full power out in CW mode. If I place the plug in position B or C I get no power out when in CW mode.

Does this indicate a bad CW filter? The filter works fine in receive mode. The only thing I have noticed is that if I switch from USB to CW the signal drops 1 S-unit when peaked for max signal in both modes.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

At this point I am using my scope with 1 meg input. If is become suspicious of the reading I switch the 10X on and take the reading that way.

An immediate problem I see is I only have 10mV P-P at the drain of Q1 in FSK mode and 0 output in CW mode. The diagram says there should be 250 mV rms there. If I pull the CW filter out of the radio, how does the CW transmit work? Does the signal then go through the USB filter or do I need to install a jumper where the CW filter was?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Yes they are RMS.

I take them at around 14.175 to 14.200 mhz with the Car Level pot advanced to the point that with the Drive Control adjusted for a peak in ALC indication at panel meter full scale deflection. Then switch to CW mode and load to approx 100 watts out and turn off SG switch. Leave Car Level and Drive control alone.

Measured values will vary depending on what test instrument you are using, length of any test jumper leads used to access the test points, line voltage.

For example 8.830mhz TIF output at the IF board and input at the RF board is shown as 0.038v. This is 38.0 mv rms rf volts or 38 x 2.828 = 107 mv P-P. So if you have approx 100mv P-P TIF you are good.

Output of the TX Mixer is 1.4v rms or 4.0v P-P. This RF drive level is now 14.175 mhz.

If you plan on doing a lot of this work suggest you invest in a RF Millivolt meter. I use a Boonton 92E. I find it loads the circuits less and just easier and faster to use.

Of coures once you get to the 1.4 volts at output of the TX Mixer the old fashioned RF probe and VTVM works great. Just have to use multi-diode probe at plate of Driver tube and control grids of the Finals. I used a Heath 309C and PK-3 probes and a IM-18 VTVM for years and still have them for fall back.

Thanks Terry. I have been talking to you since you have been helping. I don't know what made me put Dave on the last message (old age maybe).

I decided to start over from the beginning and go stage by stage this afternoon. This is what I did:
(All measurements taken with Send switch operated and Mode switch in CW position. Also, the measurements are the same in both CW and FSK modes.)

I suspected D1 or L1 was bad on the CAR-II board was bad but that is not the case. I have 720mV on CA2 leaving the CAR-II board in both CW and FSK send modes. I also have 720mV P-P on CA2 (IF5-13) on the IF board. I have 100mV P-P at the coax that connects to C92 on the IF board. On the other end of that coax where it connects to the top of T4 on the IF board I also have 100mV P-P. I would have thought the signal out of Q18 would have been stronger but maybe not.

I have 340mV at the junction of the cathode of D7 and C14 on the IF board. I have 280mV on the side of C14 where it feeds the CW filter. The signal going into the filter measures 8.830755 MHz. I only have 6mV P-P coming out of the crystal filter. Is the crystal filter used for transmit?

I connected the antenna to the radio and 20 meters is open. Tuning in CW signals in USB mode and switching to CW mode drops the signal by about 1 S-Unit when the signal is peaked for max signal in both modes.

Where do I go from here?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Are you talking Dave or Terry ? If someone is helping you off list I can back away as I have a pretty full plate right now.

I am not clear where you are measuring this 40mv P-P signal at?

Before I go I will mention that it is normal to not have a clean sine wave at TIF. It does have harmonic content and it is as you say due to LO mixing action. In this case it is coming from the VCO signal feeding back from the TX Mixer on RF board to the IF board.

This is easy to confirm with a TS-830 as you can easily unplug the VCO cable from the PLL board and the TIF signal will then be a nice clean 8.830mhz sine wave.

Dont worry about the complex waveform. Should still be able to get a reasonably close TIF measurement. It may not match exactly the levels on the TX Level Diagram,but you can compare it to the level you get with FSK carrier oscillator.

I dont use a O-scope to run TX Level diagrams once I get to the output of the TIF amp. I use a Boonton RF Millivolt meter and measure levels in rms and the "dirty" TIF signal presents no problem.

I have a new digital O-scope and it has a variety of digital filters. If I set it for a LP filter with a roll off frequency of 10mhz I can get a pretty clean 8.830 TIF sine wave display.

I dont know the Tek 2445 capability in this regard.

One final reminder is that good TIF signal level of approx 38mv rms or 107mv P-P is based on the premise that you accurately measured CA2 at the iF board of approx 300mv rms or

850mv P-P.

If that signal is not there then you would need to repeat the testing I asked you to do at the Carrier Osc board to confirm the 9vdc CW diode switching voltage is available at D1 and Q2 Buffer amp is being turned on.

I have been providing direction based on your reporting back that you have good CA-2 at Carrier board and good CA-2 at TP-5 on IF board.

If good Level at TP-5 then should have proper level at the wiper of VR-5 on the Balanced Mod. As we have discussed. No dc bias from CV and no Carrier at wiper of VR-5 then no output from the Bal Modulator.

I am pretty confident that you do have proper bias voltage from CCW to full CW on the Car Pot, but I am not certain yet that you have proper carrier output from the BM in CW mode.

Good luck.

Terry K9TW.

Dave,

I have VFO set to 14.175. With Car pot at 1200, in CW mode I get 40mV P-P in RX mode. When I flip the Send switch, the signal stays at 40 mV but it is no longer a sine wave. It is some kind of more or less sine wave with a lot of noise on it. With the Car pot at max, the noisy sinewave increases to 60 mV P-P in Send mode.

In FSK mode with Car at 1200 I get 250mV P-P in Send mode. With Car at Max I get 800 mV P-P in Send mode.

At Conn RF1-10 I get 140mV P-P in CW Send mode. I get 800mV P-P in FSK Send mode.

At the mixer output (Q1 and Q8 side of C8) I get 100 mV P-P in CW Send mode. I get 1V P-P in FSK Send mode. The signal at that point is not a sinewave but seems to have multiple signals. Probably some LO feedthrough on the mixer. The frequency counter agrees with the Kendwood readout as 14.1748 MHz.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Sorry about Q10 vs Q18. My fingers work better than what is left of my brain.

The 3 conductor plug should be positioned in forward position toward the front panel.

One thing we did not talk about is whereiyou should have the Car Level Pot set to take these measurements.

The TX Level Diagram is shown in the Service Manual. These levels were taken by Kenwood by loading the rig to approx 100 watts out at 14.175mhz and then turn the SG switch off and leave Car pot alone and Drive control alone.

Since you have no RF output in CW mode I suggest you do this for remainder of the readings:

1. VFO 14.175
2. Peak the Drive Control on receiver noise or the marker signal
3. Car Level Pot 1200
4. Heater on
5. SG switch off
6. Flip to Send to take RF drive levels

So the differences in voltages may be due to where we each have our Car Level pot set at.

Suggest you measure the voltage and frequency of the TIF signal at IF-3 Pin 2 one more time and it should be approx 250mv rms or 700mv P-P @ 8830.7mhz.

If you have close to this time to move on to the RF board. I must say this is getting a little odd as you have good output ini SSB and FSK which tells us you have good TIF level and the TX Mixer on RF Board is working which means you have good VCO (LO to the mixer).

Are you 100% certain you have no CW RF output on all bands? If so, then proceed on to the RF board with Heaters On and SG off and rig peaked as noted above.

You should have close to the values noted on the TX Level Diagram. At Conn RF-1 Pin 10 the 8.830 TIF signal level is approx 38mv rms or 108 P-P.

At output of TX Mixer should have approx 1.5v rms or 4.2v P-P rf drive at MD. At MD frequency will now be 14.175mhz transmit frequency.

If you have no RF drive or very weak at MD then need to measure the VCO level and frequency at RF-1 pin 4 and on board at TP-1. Should be close to 1.0v rms level. If no VCO try on other bands.

We are making good progress. Your Tek 2445 is perfect scope for KW Hybrid work and you apparently know how to use it and can read a schematic and can locate points on these high density boards to take measurements. This really helps.

Based on your report of no RF output in CW mode I would have thought we would have found no TIF sig at output of the IF board. TIF is not band specific and often is caused by no output from the Bal Modulator, This is why I had you start by testing for bias voltage and LO signal available. Never expected that we would be at the RF board and TX Mixer based on good RF output on other modes.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I read a little over 700mV at the drain of Q18 (actually the backside of C92 feeding the coax). I think you meant Q18 instead of Q10.

D7 and D8 are the CW switching diodes. With the mode switch in CW position, I have 2.98 volts on the anode of D7 and 2.34 volts on the cathode. I have 10.0 volts on the anode of D8 and 9.40 volts on the cathode. These voltages are there in both RX and TX, just a few 10ths of a volt lower in TX mode.

Can you confirm how the 3 pin cable ofr IF2 is supposed to plug in? It only has 3 wires but there are 5 pins on the IF board at that point. According to the chassis wiring diagram,

only the first 3 pins are used as they come from S6-1.

I don't think there is anything wrong with the CW filter and the switching diodes as the CW filter works fine in RX mode.

I have 400mV P-P on Gate 1 of Q1 instead of the 160mV when flipping Send. I also have 2400mV P-P on the drain instead of 1000mV when flipping Send.

TIF signal on Conn IF-3 is 400mV P-P and the sine wave isn't quiet as clean there as it is on the drain of Q1.

Hopefully we are making progress.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Good job. Much better.

If I understand your chart you are telling me that you have approx 640mv P-P @ 8.83077 at TP-5 in CW mode with rig flipped to Send (heaters off and SG switch off). 900mv P-P is attainable by adjusting T1 on CAR-2 board, but can do later unless you want to peak it now. 640mv will work for testing.

If this is true then you have confirmed that you have the two things you need at the Balanced Mod to produce RF output from it in CW mode. 1. Offset bias voltage and 2. Proper Carrier freq and level.

From the BM output the CW signal is routed to the Crystal IF Filter and then to Q1 the Transmit IF Amp or TIF amp. TIF signal leaves the IF board and is routed to the RF board to the TX Mixer where it is mixed with VCO to produce the actual transmit rf drive signal. No TIF signal and there will be no RF drive and no RF output. Also no VCO or low VCO level and no rf drive. Lets validate that we have TIF signal in CW mode first.

Unfortunately KW didnt provide a nice test point at the output of the Balanced Mod to measure the DSBSC signal in SSB mode or the Carrier in CW mode. However, you can get on the Drain of Q10 with a hat pin or floral arrangement pin and mini-grabber test lead. If you locate the BM ring diodes D26-D29 and then output Xfmr T10 you will see Q10. It is a metal can dual gate mosfet. Looking down on the can the Drain is the upper right lead. You should read approx 800mv P-P here. This signal is routed to the Xtal filter thru switcing diodes.

Do you have the CW filter installed. It is rare but could have a bad filter. More common to have a bad switching diode.

After signal passes thru the Xtal filter it is applied to Gate 1 of TIF amp Q1. It is also a metal can dual gate mosfet and sits outside and almost between the two filters at the inboard end. Looking down on Q1 Gate 1 is at 1200. Should have approx 160mv P-P here. The Drain is at 0600 and should have approx 1000mv P-P. TIF output is on Conn IF-3 Pin 2 and should have approx 850mv P-P here. You can jump right to measuring TIF output if you want and if good then off to the RF board.

We know that you have TIF output in FSK mode as you reported good RF output in that mode. I dont kow if you keyed rig in FSK and noted the 170hz shift or not, but not important right

now. Also, you should have noted that the RF output in FSK is lower as the 820 lowers the Finals Screen Grid voltage in FSK mode so the tubes plate dissipation is not exceeded in this high duty cycle mode.

That should be enough for now.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

This is what I am seeing:
TP-5 and CJ3-CA2 have the same levels in CW and FSK modes: 820mV P-P in RX mode. Flipping Send switch the level drops to 640mV P-P. I have a Tektronix 2445 Scope and have the probe in 10X to prevent loading the circuit.

Frequencies measured at CJ3-CA2:
RX mode FSK - 8.828414 - TX mode FSK 8.830620
RX mode LSB - 8.828414 - TX mode LSB 8.828579
RX mode USB - 8.831460 - TX mode USB 8.831625
RX mode CW - 8.831460 - TX mode CW 8.830777

Frequencies measured at TP-5:
RX mode FSK - 8.828410 - TX mode FSK 8.830616
RX mode LSB - 8.828410 - TX mode LSB 8.828575
RX mode USB - 8.831450 - TX mode USB 8.831622
RX mode CW - 8.831446 - TX mode CW 8.830773

I am using a Simpson 710 Frequency counter. Specs say 1 Meg input shunted by 30 pF. The slight differences in frequency readings between CJ3-CA2 and TP-5 is probably due to the cable capacitance of the cable between IF5-13 and CJ3-CA2.

I have been taking all of these measurements with the SG switch turned off and the heater switch turned off.

Ray AB7HE

Ray:

I mis-spoke in Item 2 when I said you cant measure carrier at TP-5 in Rx in any of the mode switch positions. There will be legitimate carrier but not of interest.

There will be Carrier at CA-2 and TP-5 in Rx in all positions of the mode switch that you should see, but it is meaningless for CW Tx operation. It was not correct for me to label it as "Leakage" signals.

It is there by design but not for Rx or Tx operation. CA-1 Carrier Osc signals are coupled to the CAR-2 board to amp Q3 and then on to TP-5 at IF board and then sampled and sent to the CCR lead to provide carrier oscillator signals for the Counter Mixer Board. So the carrier osc signals you were measuring at each position of the mode switch in Rx are there by design to feed the counter, but of no interest to us as not utilized for the BM and CW transmit.

So you will see approx 250mv rms at 8831.50 mhz in CW and LSB and 250mv at 8828.5mhz in LSB and FSK, but not used by the BM. BM is not used in Rx operation. So disregard these signal other than the low levels you measured cannot be correct if your counter is working properly. I suspect you are not using O-scope properly. Are you using a 10X probe?

What I meant to say is at CA-2 and TP-5 the only frequency and level we care about is in CW and FSK positions of the mode switch in Tx. CA-2 carrier oscillator should be approx 250mv rms @ 8830.70mhz when in CW and FSK mode when flipped to send. This is what you are trying to validate. Measure at TP-5 in FSK as you know it is working. So use it to get your O-scope set up correctly and you can see approx 850mv P-P at 8830.7mhz. Once you can read that on your O-scope now switch to CW mode and flip to send to measure carrier osc signal level at TP-5.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Yes this new format gives me problems as well.

1. You are getting proper dc bias voltage to the BM. You need to confirm you are getting the Carrier Osc signal.

2. You cannot measure any Carrier freq or level at TP-5 in RX for any position of the mode switch. You may read some leakage signals in RX mode but meaningless. The BM is only used for TX and not RX. Only time you can measure any meaningful Carrier Osc frequency or level at TP-5 is in TX with the mode switch in CW or FSK. Carrier in RX mode is applied to another Mixer called the Product Detector and it arrives at IF board on IF-4 C1A terminal. You have separate Carrier Oscillators for RX and TX.

Also, the Car Level Pot has nothing to do with the Carrier Osc levels produced on the CAR Assembly Unit. The Car level pot unbalances the balanced modulator and determines the carrier output level from the BM.

You really need to measure CA-2 produced on the CAR-2 board. If you do not have 300mv of 8830.7mhz at TP-5 in CW mode when you flip to Send then you have to work your way back from TP-5 to CAR-2 board. CA2 can be checked on the 7th terminal up on the white terminal block on the CAR-2 board. On the IF board it comes in on Conn IF-5 pin 13.

At this point you have not confirmed that you have CAR-2 Q1 Oscillator running and available.

3. The DC voltages that you measured at D1 prove that you are getting the turn on voltages for Buffer amp Q2 so if Q1 is oscillating should get CW TX Carrier at CJ-3 and on to the IF board if all connectors are good.

You may have to adjust the frequency and output level but can talk about that later.

Suggest you buy a Freq Counter. Can measure Freq roughly with O-scope. Some measure and display Freq (may or may not do so accurately) and some require using F=1/T and not accurate enough for adjusting the Oscillators in the KW hybrids.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Let's try this again. For some reason yahoo has been mangling my posts. This has been a problem ever since they went to this new stupid format they are using.

Measuring at TP-2 the voltage varies from 16 mV to .443V when adjusting the CAR control in both FSK and CW mode. On Conn IF-5 at the CV terminal, the voltage varies from .12V to 8.95V in both FSK and CW mode when adjusting the CAR control.

Also, on the FIX VOX board FIX3-11 is grounded with no key plugged in. Plugging a key in, FIX3-11 follows the key (open key up, grounded key down).

I have cleaned the contacts on the Mode switch and checked for broken wires.

At TP-5 I measure 8.831434 MHz at .64V P-P (on scope) in all positions of the mode switch without the Send switch flipped. When I flip the Send switch the voltage drops to .48V P-P. The CAR control has no affect on the signal level with the Send switch in either position.

I measure 8.97V at the CW terminal on CAR-2 when I flip the Send switch. I measure 8.94V at the anode of D1 and 8.19V at the cathode when the Send switch is flipped.

I have a couple of multimeters, a 150 MHz analog scope, 100 MHz digital scope, W7ZOI power meter, and a KA7EXM power meter. I feel comfortable taking measurements anywhere inside the radio including the Final Cage.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

For some reason I cannot read your entire response? It appears you are reporting back that you have good bias voltage available at the BM from the Car Pot. In CW TX mode you need this bias voltage and you need the local oscillator (LO) or Carrier to produce an output. Which in this case it is 8.830.70mhz CA-2 produced on the CAR-2 Unit.

You are getting CA-2 Carrier in FSK mode so it tells me the Crystal and the soldering at its pins have to be good.

If you have a RF millivolt meter or O-scope you can measure the 8830.7 mhz Carrier at the IF board at TP-5.TP-5 is tucked back in the corner under the chassis side rail. With rig in CW mode flip to send and measure the level and the frequency at TP-5. It should be approx 300mv rms or approx 850mv P-P on a scope at 8830.70mhz.

I would measure the level first before you look at it with a Freq Counter as the counter may pull the level down. If you dont have a means to measure CA-2 Carrier level and frequency then at minimum measure CW terminal at CAR-2 Unit board to make sure you are getting CW TX bias voltage.

If you remove the 2 screws that secure the cover you will see a white 10 pin connector. The 3rd pin from the Crystal is the CW terminal. When you flip to send in CW mode should see approx 9.0vdc here. If you have 9vdc and still no output then suspect bad switching diode D1. D1 is close to the Crystal and you can measure the voltage at its anode and cathode. When you flip to send in CW mode should read approx 9vdc on the anode and approx 8.3vdc on the cathode. Note: The 9vdc will depend on where the AVR regulated 9vdc has been set too.

Topic: 45375 Message: 45493

Just to make certain I understand what you are reporting:

1. With IF-2 in Pos A (toward rear panel) you have good TX output in all modes and good RX thru the SSB filter ?

2. With IF-2 in Pos B you have good TX output in LSB, USB, FSK modes thru the SSB filter. You have no TX output in CW mode thru the CW filter but have good RX in CW mode thru the CW filter?

3. With IF-2 in Pos C (toward front panel) you have good TX output in LSB, USB modes thru the SSB filter. You have good TX output in FSK mode thru the CW filter. You have no TX output in CW mode thru the CW filter, but you do have good RX thru the CW filter?

Is configuration 3 what we are talking about?

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK I forgot to give you the Anode voltages of D7 and D8 but you can just subtract approx 0.65vdc for the turn on voltage.

280mv P-P is high by my measurements, but if you read close to same in FSK-T then call it good. Certainly better than be too low.

6 mv P-P at output in CW-T is definitely a problem. As I said you can jumper the filter with a .047uf cap and see if you get CW Tx.

Is this the factory YG-88C filter?

I believe it has center frequency of 8830.7 mhz.and bandwidth of 500hz at -6dB.
I have never swept one.

It would not seem likely that you would have bad solder connections if the filter is working in FSK mode. Are you 100% certain you are not using the SSB filter in FSK mode?

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

My voltages at D7 and D8 are virtually identical to yours. I had previously measured the levels at D7 and D8. I measured 280mV P-P where C14 connects to the CW filter and only 6mV P-P out of the filter. But that was before I changed the cable to position A. I will have to move the cable back to C and re-measure tomorrow. I will also pull the IF board out and resolder the CW crystal filter connections. It may be bad solder connections as you suggest.

I just made my first contact in 17 years on 7.020 with W5TZC about 30 mins ago. He gave me a 579 which is pretty good considering my antenna is only 8 feet off the ground. I also still have to address why they final isn't tuning properly on 40 meters. It tuned max power with plate knob pointer sitting on the 5 of 3.5. It dips at 14 on 20 meters.

If I can get the CW filter issue worked out I will go through a complete tuneup of the radio following the service manual procedures.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

It is easy to test CW filter switching diodes D7 and D8. I thought you already did this and reported good?

As previously noted my plug is in C all the way toward the front panel.

Conn IF-2 pins 4 and 5 have approx 12.9vdc on them in Rx and Tx for CW-R, CW-T, FSK-R, and FSK-T.

The cathode of D7 is:
CW-R and FSK-R = 2.90vdc
CW-T and FSK- T = 2.90vdc

The cathode of D8 is : (Note: When you connect voltmeter back ground noise will drop significantly).
CW-R and FSK-R = 10.0vdc
CW-T and FSK-T = 9.80vdc

The reading will be different as the diodes are biased to different current levels. You can see the difference in the supply resistors for each diode.

I have never been able to measure TX level diagram RF voltages accurately using a 1X scope probe. It will pull your ALC indication down from FSD (40 over) to approx 25 over.

You should be able to measure the 8.830mhz TIF signal level at the input and output of the CW Xtal filter. I thought we did this a long time ago?

It is normal for the filters to have an insertion loss. Should have a minimum of approx 25mv rms at D7 input and minimum of approx 19mv rms at D8 output.

Here are my RF level measurements at D7 and D8:

Test conditons: 14.175mhz, Heater on , SG switch off, CW mode, Drive control peaked, Car Pot at 2.5 (for full scale ALC deflection or 40 over)

Boonton 92E (using 10x scope probe very close to same levels)
D7 = 58mv
D8 = 25mv

You can jumper across your CW filter with a couple of mini-grabber test leads with a 0.047uf capacitor in series.

Could have good switching diodes and good filter but bad solder connections at the filter?

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I have made a discovery that will probably tell us where the actual problem is. I was googling how to replace CW filter and found this link:
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2

So I downloaded the operators manual and looked at page 34. Kenwood is perfectly clear about this. If the plug is in position A, the CW filter is bypassed.

I put the plug in position A and can tune to full power out in CW mode. If I place the plug in position B or C I get no power out when in CW mode.

Does this indicate a bad CW filter? The filter works fine in receive mode. The only thing I have noticed is that if I switch from USB to CW the signal drops 1 S-unit when peaked for max signal in both modes.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

At this point I am using my scope with 1 meg input. If is become suspicious of the reading I switch the 10X on and take the reading that way.

An immediate problem I see is I only have 10mV P-P at the drain of Q1 in FSK mode and 0 output in CW mode. The diagram says there should be 250 mV rms there. If I pull the CW filter out of the radio, how does the CW transmit work? Does the signal then go through the USB filter or do I need to install a jumper where the CW filter was?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Yes they are RMS.

I take them at around 14.175 to 14.200 mhz with the Car Level pot advanced to the point that with the Drive Control adjusted for a peak in ALC indication at panel meter full scale deflection. Then switch to CW mode and load to approx 100 watts out and turn off SG switch. Leave Car Level and Drive control alone.

Measured values will vary depending on what test instrument you are using, length of any test jumper leads used to access the test points, line voltage.

For example 8.830mhz TIF output at the IF board and input at the RF board is shown as 0.038v. This is 38.0 mv rms rf volts or 38 x 2.828 = 107 mv P-P. So if you have approx 100mv P-P TIF you are good.

Output of the TX Mixer is 1.4v rms or 4.0v P-P. This RF drive level is now 14.175 mhz.

If you plan on doing a lot of this work suggest you invest in a RF Millivolt meter. I use a Boonton 92E. I find it loads the circuits less and just easier and faster to use.

Of coures once you get to the 1.4 volts at output of the TX Mixer the old fashioned RF probe and VTVM works great. Just have to use multi-diode probe at plate of Driver tube and control grids of the Finals. I used a Heath 309C and PK-3 probes and a IM-18 VTVM for years and still have them for fall back.

Thanks Terry. I have been talking to you since you have been helping. I don't know what made me put Dave on the last message (old age maybe).

I decided to start over from the beginning and go stage by stage this afternoon. This is what I did:
(All measurements taken with Send switch operated and Mode switch in CW position. Also, the measurements are the same in both CW and FSK modes.)

I suspected D1 or L1 was bad on the CAR-II board was bad but that is not the case. I have 720mV on CA2 leaving the CAR-II board in both CW and FSK send modes. I also have 720mV P-P on CA2 (IF5-13) on the IF board. I have 100mV P-P at the coax that connects to C92 on the IF board. On the other end of that coax where it connects to the top of T4 on the IF board I also have 100mV P-P. I would have thought the signal out of Q18 would have been stronger but maybe not.

I have 340mV at the junction of the cathode of D7 and C14 on the IF board. I have 280mV on the side of C14 where it feeds the CW filter. The signal going into the filter measures 8.830755 MHz. I only have 6mV P-P coming out of the crystal filter. Is the crystal filter used for transmit?

I connected the antenna to the radio and 20 meters is open. Tuning in CW signals in USB mode and switching to CW mode drops the signal by about 1 S-Unit when the signal is peaked for max signal in both modes.

Where do I go from here?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Are you talking Dave or Terry ? If someone is helping you off list I can back away as I have a pretty full plate right now.

I am not clear where you are measuring this 40mv P-P signal at?

Before I go I will mention that it is normal to not have a clean sine wave at TIF. It does have harmonic content and it is as you say due to LO mixing action. In this case it is coming from the VCO signal feeding back from the TX Mixer on RF board to the IF board.

This is easy to confirm with a TS-830 as you can easily unplug the VCO cable from the PLL board and the TIF signal will then be a nice clean 8.830mhz sine wave.

Dont worry about the complex waveform. Should still be able to get a reasonably close TIF measurement. It may not match exactly the levels on the TX Level Diagram,but you can compare it to the level you get with FSK carrier oscillator.

I dont use a O-scope to run TX Level diagrams once I get to the output of the TIF amp. I use a Boonton RF Millivolt meter and measure levels in rms and the "dirty" TIF signal presents no problem.

I have a new digital O-scope and it has a variety of digital filters. If I set it for a LP filter with a roll off frequency of 10mhz I can get a pretty clean 8.830 TIF sine wave display.

I dont know the Tek 2445 capability in this regard.

One final reminder is that good TIF signal level of approx 38mv rms or 107mv P-P is based on the premise that you accurately measured CA2 at the iF board of approx 300mv rms or 850mv P-P.

If that signal is not there then you would need to repeat the testing I asked you to do at the Carrier Osc board to confirm the 9vdc CW diode switching voltage is available at D1 and Q2 Buffer amp is being turned on.

I have been providing direction based on your reporting back that you have good CA-2 at Carrier board and good CA-2 at TP-5 on IF board.

If good Level at TP-5 then should have proper level at the wiper of VR-5 on the Balanced Mod. As we have discussed. No dc bias from CV and no Carrier at wiper of VR-5 then no output from the Bal Modulator.

I am pretty confident that you do have proper bias voltage from CCW to full CW on the Car Pot, but I am not certain yet that you have proper carrier output from the BM in CW mode.

Good luck.

Terry K9TW.

Dave,

I have VFO set to 14.175. With Car pot at 1200, in CW mode I get 40mV P-P in RX mode. When I flip the Send switch, the signal stays at 40 mV but it is no longer a sine wave. It is some kind of more or less sine wave with a lot of noise on it. With the Car pot at max, the noisy sinewave increases to 60 mV P-P in Send mode.

In FSK mode with Car at 1200 I get 250mV P-P in Send mode. With Car at Max I get 800 mV P-P in Send mode.

At Conn RF1-10 I get 140mV P-P in CW Send mode. I get 800mV P-P in FSK Send mode.

At the mixer output (Q1 and Q8 side of C8) I get 100 mV P-P in CW Send mode. I get 1V P-P in FSK Send mode. The signal at that point is not a sinewave but seems to have multiple signals. Probably some LO feedthrough on the mixer. The frequency counter agrees with the Kendwood readout as 14.1748 MHz.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Sorry about Q10 vs Q18. My fingers work better than what is left of my brain.

The 3 conductor plug should be positioned in forward position toward the front panel.

One thing we did not talk about is whereiyou should have the Car Level Pot set to take these measurements.

The TX Level Diagram is shown in the Service Manual. These levels were taken by Kenwood by loading the rig to approx 100 watts out at 14.175mhz and then turn the SG switch off and leave Car pot alone and Drive control alone.

Since you have no RF output in CW mode I suggest you do this for remainder of the readings:

1. VFO 14.175
2. Peak the Drive Control on receiver noise or the marker signal
3. Car Level Pot 1200
4. Heater on
5. SG switch off
6. Flip to Send to take RF drive levels

So the differences in voltages may be due to where we each have our Car Level pot set at.

Suggest you measure the voltage and frequency of the TIF signal at IF-3 Pin 2 one more time and it should be approx 250mv rms or 700mv P-P @ 8830.7mhz.

If you have close to this time to move on to the RF board. I must say this is getting a little odd as you have good output ini SSB and FSK which tells us you have good TIF level and the TX Mixer on RF Board is working which means you have good VCO (LO to the mixer).

Are you 100% certain you have no CW RF output on all bands? If so, then proceed on to the RF board with Heaters On and SG off and rig peaked as noted above.

You should have close to the values noted on the TX Level Diagram. At Conn RF-1 Pin 10 the 8.830 TIF signal level is approx 38mv rms or 108 P-P.

At output of TX Mixer should have approx 1.5v rms or 4.2v P-P rf drive at MD. At MD frequency will now be 14.175mhz transmit frequency.

If you have no RF drive or very weak at MD then need to measure the VCO level and frequency at RF-1 pin 4 and on board at TP-1. Should be close to 1.0v rms level. If no VCO try on other bands.

We are making good progress. Your Tek 2445 is perfect scope for KW Hybrid work and you apparently know how to use it and can read a schematic and can locate points on these high

density boards to take measurements. This really helps.

Based on your report of no RF output in CW mode I would have thought we would have found no TIF sig at output of the IF board. TIF is not band specific and often is caused by no output from the Bal Modulator, This is why I had you start by testing for bias voltage and LO signal available. Never expected that we would be at the RF board and TX Mixer based on good RF output on other modes.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I read a little over 700mV at the drain of Q18 (actually the backside of C92 feeding the coax). I think you meant Q18 instead of Q10.

D7 and D8 are the CW switching diodes. With the mode switch in CW position, I have 2.98 volts on the anode of D7 and 2.34 volts on the cathode. I have 10.0 volts on the anode of D8 and 9.40 volts on the cathode. These voltages are there in both RX and TX, just a few 10ths of a volt lower in TX mode.

Can you confirm how the 3 pin cable ofr IF2 is supposed to plug in? It only has 3 wires but there are 5 pins on the IF board at that point. According to the chassis wiring diagram, only the first 3 pins are used as they come from S6-1.

I don't think there is anything wrong with the CW filter and the switching diodes as the CW filter works fine in RX mode.

I have 400mV P-P on Gate 1 of Q1 instead of the 160mV when flipping Send. I also have 2400mV P-P on the drain instead of 1000mV when flipping Send.

TIF signal on Conn IF-3 is 400mV P-P and the sine wave isn't quiet as clean there as it is on the drain of Q1.

Hopefully we are making progress.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Good job. Much better.

If I understand your chart you are telling me that you have approx 640mv P-P @ 8.83077 at TP-5 in CW mode with rig flipped to Send (heaters off and SG switch off). 900mv P-P is attainable by adjusting T1 on CAR-2 board, but can do later unless you want to peak it now. 640mv will work for testing.

If this is true then you have confirmed that you have the two things you need at the Balanced Mod to produce RF output from it in CW mode. 1. Offset bias voltage and 2. Proper Carrier freq and level.

From the BM output the CW signal is routed to the Crystal IF Filter and then to Q1 the Transmit IF Amp or TIF amp. TIF signal leaves the IF board and is routed to the RF board to the TX Mixer where it is mixed with VCO to produce the actual transmit rf drive signal. No TIF signal and there will be no RF drive and no RF output. Also no VCO or low VCO level and no rf drive. Lets validate that we have TIF signal in CW mode first.

Unfortunately KW didnt provide a nice test point at the output of the Balanced Mod to measure the DSBSC signal in SSB mode or the Carrier in CW mode. However, you can get on the Drain of Q10 with a hat pin or floral arrangement pin and mini-grabber test lead. If you locate the BM ring diodes D26-D29 and then output Xfmr T10 you will see Q10. It is a metal can dual gate mosfet. Looking down on the can the Drain is the upper right lead. You should read approx 800mv P-P here. This signal is routed to the Xtal filter thru switcing diodes.

Do you have the CW filter installed. It is rare but could have a bad filter. More common to have a bad switching diode.

After signal passes thru the Xtal filter it is applied to Gate 1 of TIF amp Q1. It is also a metal can dual gate mosfet and sits outside and almost between the two filters at the inboard end. Looking down on Q1 Gate 1 is at 1200. Should have approx 160mv P-P here. The Drain is at 0600 and should have approx 1000mv P-P. TIF output is on Conn IF-3 Pin 2 and should have approx 850mv P-P here. You can jump right to measuring TIF output if you want and if good then off to the RF board.

We know that you have TIF output in FSK mode as you reported good RF output in that mode. I dont kow if you keyed rig in FSK and noted the 170hz shift or not, but not important right now. Also, you should have noted that the RF output in FSK is lower as the 820 lowers the Finals Screen Grid voltage in FSK mode so the tubes plate dissipation is not exceeded in this high duty cycle mode.

That should be enough for now.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

This is what I am seeing:
TP-5 and CJ3-CA2 have the same levels in CW and FSK modes: 820mV P-P in RX mode. Flipping Send switch the level drops to 640mV P-P. I have a Tektronix 2445 Scope and have the probe in 10X to prevent loading the circuit.

Frequencies measured at CJ3-CA2:
RX mode FSK - 8.828414 - TX mode FSK 8.830620
RX mode LSB - 8.828414 - TX mode LSB 8.828579
RX mode USB - 8.831460 - TX mode USB 8.831625
RX mode CW - 8.831460 - TX mode CW 8.830777

Frequencies measured at TP-5:
RX mode FSK - 8.828410 - TX mode FSK 8.830616
RX mode LSB - 8.828410 - TX mode LSB 8.828575
RX mode USB - 8.831450 - TX mode USB 8.831622
RX mode CW - 8.831446 - TX mode CW 8.830773

I am using a Simpson 710 Frequency counter. Specs say 1 Meg input shunted by 30 pF. The slight differences in frequency readings between CJ3-CA2 and TP-5 is probably due to the

cable capacitance of the cable between IF5-13 and CJ3-CA2.

I have been taking all of these measurements with the SG switch turned off and the heater switch turned off.

Ray AB7HE

Ray:

I mis-spoke in Item 2 when I said you cant measure carrier at TP-5 in Rx in any of the mode switch positions. There will be legitimate carrier but not of interest.

There will be Carrier at CA-2 and TP-5 in Rx in all positions of the mode switch that you should see, but it is meaningless for CW Tx operation. It was not correct for me to label it as "Leakage" signals.

It is there by design but not for Rx or Tx operation. CA-1 Carrier Osc signals are coupled to the CAR-2 board to amp Q3 and then on to TP-5 at IF board and then sampled and sent to the CCR lead to provide carrier oscillator signals for the Counter Mixer Board. So the carrier osc signals you were measuring at each position of the mode switch in Rx are there by design to feed the counter, but of no interest to us as not utilized for the BM and CW transmit.

So you will see approx 250mv rms at 8831.50 mhz in CW and LSB and 250mv at 8828.5mhz in LSB and FSK, but not used by the BM. BM is not used in Rx operation. So disregard these signal other than the low levels you measured cannot be correct if your counter is working properly. I suspect you are not using O-scope properly. Are you using a 10X probe?

What I meant to say is at CA-2 and TP-5 the only frequency and level we care about is in CW and FSK positions of the mode switch in Tx. CA-2 carrier oscillator should be approx 250mv rms @ 8830.70mhz when in CW and FSK mode when flipped to send. This is what you are trying to validate. Measure at TP-5 in FSK as you know it is working. So use it to get your O-scope set up correctly and you can see approx 850mv P-P at 8830.7mhz. Once you can read that on your O-scope now switch to CW mode and flip to send to measure carrier osc signal level at TP-5.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Yes this new format gives me problems as well.

1. You are getting proper dc bias voltage to the BM. You need to confirm you are getting the Carrier Osc signal.

2. You cannot measure any Carrier freq or level at TP-5 in RX for any position of the mode switch. You may read some leakage signals in RX mode but meaningless. The BM is only used for TX and not RX. Only time you can measure any meaningful Carrier Osc frequency or level at TP-5 is in TX with the mode switch in CW or FSK. Carrier in RX mode is applied to another Mixer called the Product Detector and it arrives at IF board on IF-4 C1A terminal. You have separate Carrier Oscillators for RX and TX.

Also, the Car Level Pot has nothing to do with the Carrier Osc levels produced on the CAR Assembly Unit. The Car level pot unbalances the balanced modulator and determines the carrier output level from the BM.

You really need to measure CA-2 produced on the CAR-2 board. If you do not have 300mv of 8830.7mhz at TP-5 in CW mode when you flip to Send then you have to work your way back from TP-5 to CAR-2 board. CA2 can be checked on the 7th terminal up on the white terminal block on the CAR-2 board. On the IF board it comes in on Conn IF-5 pin 13.

At this point you have not confirmed that you have CAR-2 Q1 Oscillator running and available.

3. The DC voltages that you measured at D1 prove that you are getting the turn on voltages for Buffer amp Q2 so if Q1 is oscillating should get CW TX Carrier at CJ-3 and on to the IF board if all connectors are good.

You may have to adjust the frequency and output level but can talk about that later.

Suggest you buy a Freq Counter. Can measure Freq roughly with O-scope. Some measure and display Freq (may or may not do so accurately) and some require using F=1/T and not accurate enough for adjusting the Oscillators in the KW hybrids.

Topic: 45375 Message: 45494

I meant Cathode voltages but I think you get the idea. Measure the Anode and Cathode to ensure both diodes are being switched on. Should see approx 0.65 vdc drop across D7 and D8 as they are silicon diodes.

Not likely bad but if you need to replace I offer the following:

Should you need a diode do not use a NTE 177 sub. These are 1S1587 fast switching diodes with a fast reverse recovery time of approx 2 ns so I would not use a general purpose silicon diode as NTE sub guide suggests. Can use a NTE 519, but it has a recovery time of approx 70 ns.

I think a 1N914 or 1N4148 would be better choice at 4ns..These are still pretty commonly available.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK I forgot to give you the Anode voltages of D7 and D8 but you can just subtract approx 0.65vdc for the turn on voltage.

280mv P-P is high by my measurements, but if you read close to same in FSK-T then call it good. Certainly better than be too low.

6 mv P-P at output in CW-T is definitely a problem. As I said you can jumper the filter with a .047uf cap and see if you get CW Tx.

Is this the factory YG-88C filter?

I believe it has center frequency of 8830.7 mhz.and bandwidth of 500hz at -6dB.
I have never swept one.

It would not seem likely that you would have bad solder connections if the filter is working in FSK mode. Are you 100% certain you are not using the SSB filter in FSK mode?

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

My voltages at D7 and D8 are virtually identical to yours. I had previously measured the levels at D7 and D8. I measured 280mV P-P where C14 connects to the CW filter and only 6mV P-P out of the filter. But that was before I changed the cable to position A. I will have to move the cable back to C and re-measure tomorrow. I will also pull the IF board out and resolder the CW crystal filter connections. It may be bad solder connections as you suggest.

I just made my first contact in 17 years on 7.020 with W5TZC about 30 mins ago. He gave me a 579 which is pretty good considering my antenna is only 8 feet off the ground. I also still have to address why they final isn't tuning properly on 40 meters. It tuned max power with plate knob pointer sitting on the 5 of 3.5. It dips at 14 on 20 meters.

If I can get the CW filter issue worked out I will go through a complete tuneup of the radio following the service manual procedures.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

It is easy to test CW filter switching diodes D7 and D8. I thought you already did this and reported good?

As previously noted my plug is in C all the way toward the front panel.

Conn IF-2 pins 4 and 5 have approx 12.9vdc on them in Rx and Tx for CW-R, CW-T, FSK-R, and FSK-T.

The cathode of D7 is:
CW-R and FSK-R = 2.90vdc
CW-T and FSK- T = 2.90vdc

The cathode of D8 is : (Note: When you connect voltmeter back ground noise will drop significantly).
CW-R and FSK-R = 10.0vdc
CW-T and FSK-T = 9.80vdc

The reading will be different as the diodes are biased to different current levels. You can see the difference in the supply resistors for each diode.

I have never been able to measure TX level diagram RF voltages accurately using a 1X scope probe. It will pull your ALC indication down from FSD (40 over) to approx 25 over.

You should be able to measure the 8.830mhz TIF signal level at the input and output of the CW Xtal filter. I thought we did this a long time ago?

It is normal for the filters to have an insertion loss. Should have a minimum of approx 25mv rms at D7 input and minimum of approx 19mv rms at D8 output.

Here are my RF level measurements at D7 and D8:

Test conditons: 14.175mhz, Heater on , SG switch off, CW mode, Drive control peaked, Car Pot at 2.5 (for full scale ALC deflection or 40 over)

Boonton 92E (using 10x scope probe very close to same levels)
D7 = 58mv
D8 = 25mv

You can jumper across your CW filter with a couple of mini-grabber test leads with a 0.047uf capacitor in series.

Could have good switching diodes and good filter but bad solder connections at the filter?

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I have made a discovery that will probably tell us where the actual problem is. I was googling how to replace CW filter and found this link:
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2

So I downloaded the operators manual and looked at page 34. Kenwood is perfectly clear about this. If the plug is in position A, the CW filter is bypassed.

I put the plug in position A and can tune to full power out in CW mode. If I place the plug in position B or C I get no power out when in CW mode.

Does this indicate a bad CW filter? The filter works fine in receive mode. The only thing I have noticed is that if I switch from USB to CW the signal drops 1 S-unit when peaked for max signal in both modes.

Ray AB7HE

Terry,

At this point I am using my scope with 1 meg input. If is become suspicious of the reading I switch the 10X on and take the reading that way.

An immediate problem I see is I only have 10mV P-P at the drain of Q1 in FSK mode and 0 output in CW mode. The diagram says there should be 250 mV rms there. If I pull the CW filter out of the radio, how does the CW transmit work? Does the signal then go through the USB filter or do I need to install a jumper where the CW filter was?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Yes they are RMS.

I take them at around 14.175 to 14.200 mhz with the Car Level pot advanced to the point that with the Drive Control adjusted for a peak in ALC indication at panel meter full scale deflection. Then switch to CW mode and load to approx 100 watts out and turn off SG switch. Leave Car Level and Drive control alone.

Measured values will vary depending on what test instrument you are using, length of any test jumper leads used to access the test points, line voltage.

For example 8.830mhz TIF output at the IF board and input at the RF board is shown as 0.038v. This is 38.0 mv rms rf volts or 38 x 2.828 = 107 mv P-P. So if you have approx 100mv P-P TIF you are good.

Output of the TX Mixer is 1.4v rms or 4.0v P-P. This RF drive level is now 14.175 mhz.

If you plan on doing a lot of this work suggest you invest in a RF Millivolt meter. I use a Boonton 92E. I find it loads the circuits less and just easier and faster to use.

Of coures once you get to the 1.4 volts at output of the TX Mixer the old fashioned RF probe and VTVM works great. Just have to use multi-diode probe at plate of Driver tube and control grids of the Finals. I used a Heath 309C and PK-3 probes and a IM-18 VTVM for years and still have them for fall back.

(All measurements taken with Send switch operated and Mode switch in CW position. Also, the measurements are the same in both CW and FSK modes.)

I suspected D1 or L1 was bad on the CAR-II board was bad but that is not the case. I have 720mV on CA2 leaving the CAR-II board in both CW and FSK send modes. I also have 720mV P-P on CA2 (IF5-13) on the IF board. I have 100mV P-P at the coax that connects to C92 on the IF board. On the other end of that coax where it connects to the top of T4 on the IF board I also have 100mV P-P. I would have thought the signal out of Q18 would have been stronger but maybe not.

I have 340mV at the junction of the cathode of D7 and C14 on the IF board. I have 280mV on the side of C14 where it feeds the CW filter. The signal going into the filter measures 8.830755 MHz. I only have 6mV P-P coming out of the crystal filter. Is the crystal filter used for transmit?

I connected the antenna to the radio and 20 meters is open. Tuning in CW signals in USB mode and switching to CW mode drops the signal by about 1 S-Unit when the signal is peaked for max signal in both modes.

Where do I go from here?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Are you talking Dave or Terry ? If someone is helping you off list I can back away as I have a pretty full plate right now.

I am not clear where you are measuring this 40mv P-P signal at?

Before I go I will mention that it is normal to not have a clean sine wave at TIF. It does have harmonic content and it is as you say due to LO mixing action. In this case it is coming from the VCO signal feeding back from the TX Mixer on RF board to the IF board.

This is easy to confirm with a TS-830 as you can easily unplug the VCO cable from the PLL board and the TIF signal will then be a nice clean 8.830mhz sine wave.

Dont worry about the complex waveform. Should still be able to get a reasonably close TIF measurement. It may not match exactly the levels on the TX Level Diagram,but you can compare it to the level you get with FSK carrier oscillator.

I dont use a O-scope to run TX Level diagrams once I get to the output of the TIF amp. I use a Boonton RF Millivolt meter and measure levels in rms and the "dirty" TIF signal presents no problem.

I have a new digital O-scope and it has a variety of digital filters. If I set it for a LP filter with a roll off frequency of 10mhz I can get a pretty clean 8.830 TIF sine wave display.

I dont know the Tek 2445 capability in this regard.

One final reminder is that good TIF signal level of approx 38mv rms or 107mv P-P is based on the premise that you accurately measured CA2 at the iF board of approx 300mv rms or 850mv P-P.

If that signal is not there then you would need to repeat the testing I asked you to do at the Carrier Osc board to confirm the 9vdc CW diode switching voltage is available at D1 and Q2 Buffer amp is being turned on.

I have been providing direction based on your reporting back that you have good CA-2 at Carrier board and good CA-2 at TP-5 on IF board.

If good Level at TP-5 then should have proper level at the wiper of VR-5 on the Balanced Mod. As we have discussed. No dc bias from CV and no Carrier at wiper of VR-5 then no output from the Bal Modulator.

I am pretty confident that you do have proper bias voltage from CCW to full CW on the Car Pot, but I am not certain yet that you have proper carrier output from the BM in CW mode.

Good luck.

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Dave,

I have VFO set to 14.175. With Car pot at 1200, in CW mode I get 40mV P-P in RX mode. When I flip the Send switch, the signal stays at 40 mV but it is no longer a sine wave. It is some kind of more or less sine wave with a lot of noise on it. With the Car pot at max, the noisy sinewave increases to 60 mV P-P in Send mode.

In FSK mode with Car at 1200 I get 250mV P-P in Send mode. With Car at Max I get 800 mV P-P in Send mode.

At Conn RF1-10 I get 140mV P-P in CW Send mode. I get 800mV P-P in FSK Send mode.

At the mixer output (Q1 and Q8 side of C8) I get 100 mV P-P in CW Send mode. I get 1V P-P in FSK Send mode. The signal at that point is not a sinewave but seems to have multiple signals. Probably some LO feedthrough on the mixer. The frequency counter agrees with the Kendwood readout as 14.1748 MHz.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Sorry about Q10 vs Q18. My fingers work better than what is left of my brain.

The 3 conductor plug should be positioned in forward position toward the front panel.

One thing we did not talk about is whereiyou should have the Car Level Pot set to take these measurements.

The TX Level Diagram is shown in the Service Manual. These levels were taken by Kenwood by loading the rig to approx 100 watts out at 14.175mhz and then turn the SG switch off and leave Car pot alone and Drive control alone.

Since you have no RF output in CW mode I suggest you do this for remainder of the readings:

1. VFO 14.175
2. Peak the Drive Control on receiver noise or the marker signal
3. Car Level Pot 1200
4. Heater on
5. SG switch off
6. Flip to Send to take RF drive levels

So the differences in voltages may be due to where we each have our Car Level pot set at.

Suggest you measure the voltage and frequency of the TIF signal at IF-3 Pin 2 one more time and it should be approx 250mv rms or 700mv P-P @ 8830.7mhz.

If you have close to this time to move on to the RF board. I must say this is getting a little odd as you have good output ini SSB and FSK which tells us you have good TIF level and the TX Mixer on RF Board is working which means you have good VCO (LO to the mixer).

Are you 100% certain you have no CW RF output on all bands? If so, then proceed on to the RF board with Heaters On and SG off and rig peaked as noted above.

You should have close to the values noted on the TX Level Diagram. At Conn RF-1 Pin 10 the 8.830 TIF signal level is approx 38mv rms or 108 P-P.

At output of TX Mixer should have approx 1.5v rms or 4.2v P-P rf drive at MD. At MD frequency will now be 14.175mhz transmit frequency.

If you have no RF drive or very weak at MD then need to measure the VCO level and frequency at RF-1 pin 4 and on board at TP-1. Should be close to 1.0v rms level. If no VCO try on other bands.

We are making good progress. Your Tek 2445 is perfect scope for KW Hybrid work and you apparently know how to use it and can read a schematic and can locate points on these high

density boards to take measurements. This really helps.

Based on your report of no RF output in CW mode I would have thought we would have found no TIF sig at output of the IF board. TIF is not band specific and often is caused by no output from the Bal Modulator, This is why I had you start by testing for bias voltage and LO signal available. Never expected that we would be at the RF board and TX Mixer based on good RF output on other modes.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I read a little over 700mV at the drain of Q18 (actually the backside of C92 feeding the coax). I think you meant Q18 instead of Q10.

D7 and D8 are the CW switching diodes. With the mode switch in CW position, I have 2.98 volts on the anode of D7 and 2.34 volts on the cathode. I have 10.0 volts on the anode of D8 and 9.40 volts on the cathode. These voltages are there in both RX and TX, just a few 10ths of a volt lower in TX mode.

Can you confirm how the 3 pin cable ofr IF2 is supposed to plug in? It only has 3 wires but there are 5 pins on the IF board at that point. According to the chassis wiring diagram, only the first 3 pins are used as they come from S6-1.

I don't think there is anything wrong with the CW filter and the switching diodes as the CW filter works fine in RX mode.

I have 400mV P-P on Gate 1 of Q1 instead of the 160mV when flipping Send. I also have 2400mV P-P on the drain instead of 1000mV when flipping Send.

TIF signal on Conn IF-3 is 400mV P-P and the sine wave isn't quiet as clean there as it is on the drain of Q1.

Hopefully we are making progress.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Good job. Much better.

If I understand your chart you are telling me that you have approx 640mv P-P @ 8.83077 at TP-5 in CW mode with rig flipped to Send (heaters off and SG switch off). 900mv P-P is attainable by adjusting T1 on CAR-2 board, but can do later unless you want to peak it now. 640mv will work for testing.

If this is true then you have confirmed that you have the two things you need at the Balanced Mod to produce RF output from it in CW mode. 1. Offset bias voltage and 2. Proper Carrier freq and level.

From the BM output the CW signal is routed to the Crystal IF Filter and then to Q1 the Transmit IF Amp or TIF amp. TIF signal leaves the IF board and is routed to the RF board to the TX Mixer where it is mixed with VCO to produce the actual transmit rf drive signal. No TIF signal and there will be no RF drive and no RF output. Also no VCO or low VCO level and no rf drive. Lets validate that we have TIF signal in CW mode first.

Unfortunately KW didnt provide a nice test point at the output of the Balanced Mod to measure the DSBSC signal in SSB mode or the Carrier in CW mode. However, you can get on the Drain of Q10 with a hat pin or floral arrangement pin and mini-grabber test lead. If you locate the BM ring diodes D26-D29 and then output Xfmr T10 you will see Q10. It is a metal can dual gate mosfet. Looking down on the can the Drain is the upper right lead. You should read approx 800mv P-P here. This signal is routed to the Xtal filter thru switcing diodes.

Do you have the CW filter installed. It is rare but could have a bad filter. More common to have a bad switching diode.

After signal passes thru the Xtal filter it is applied to Gate 1 of TIF amp Q1. It is also a metal can dual gate mosfet and sits outside and almost between the two filters at the inboard end. Looking down on Q1 Gate 1 is at 1200. Should have approx 160mv P-P here. The Drain is at 0600 and should have approx 1000mv P-P. TIF output is on Conn IF-3 Pin 2 and should have approx 850mv P-P here. You can jump right to measuring TIF output if you want and if good then off to the RF board.

We know that you have TIF output in FSK mode as you reported good RF output in that mode. I dont kow if you keyed rig in FSK and noted the 170hz shift or not, but not important right now. Also, you should have noted that the RF output in FSK is lower as the 820 lowers the Finals Screen Grid voltage in FSK mode so the tubes plate dissipation is not exceeded in this high duty cycle mode.

That should be enough for now.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

This is what I am seeing:
TP-5 and CJ3-CA2 have the same levels in CW and FSK modes: 820mV P-P in RX mode. Flipping Send switch the level drops to 640mV P-P. I have a Tektronix 2445 Scope and have the probe in 10X to prevent loading the circuit.

Frequencies measured at CJ3-CA2:
RX mode FSK - 8.828414 - TX mode FSK 8.830620
RX mode LSB - 8.828414 - TX mode LSB 8.828579
RX mode USB - 8.831460 - TX mode USB 8.831625
RX mode CW - 8.831460 - TX mode CW 8.830777

Frequencies measured at TP-5:
RX mode FSK - 8.828410 - TX mode FSK 8.830616
RX mode LSB - 8.828410 - TX mode LSB 8.828575
RX mode USB - 8.831450 - TX mode USB 8.831622
RX mode CW - 8.831446 - TX mode CW 8.830773

I am using a Simpson 710 Frequency counter. Specs say 1 Meg input shunted by 30 pF. The slight differences in frequency readings between CJ3-CA2 and TP-5 is probably due to the

cable capacitance of the cable between IF5-13 and CJ3-CA2.

I have been taking all of these measurements with the SG switch turned off and the heater switch turned off.

Ray:

I mis-spoke in Item 2 when I said you cant measure carrier at TP-5 in Rx in any of the mode switch positions. There will be legitimate carrier but not of interest.

There will be Carrier at CA-2 and TP-5 in Rx in all positions of the mode switch that you should see, but it is meaningless for CW Tx operation. It was not correct for me to label it as "Leakage" signals.

It is there by design but not for Rx or Tx operation. CA-1 Carrier Osc signals are coupled to the CAR-2 board to amp Q3 and then on to TP-5 at IF board and then sampled and sent to the CCR lead to provide carrier oscillator signals for the Counter Mixer Board. So the carrier osc signals you were measuring at each position of the mode switch in Rx are there by design to feed the counter, but of no interest to us as not utilized for the BM and CW transmit.

So you will see approx 250mv rms at 8831.50 mhz in CW and LSB and 250mv at 8828.5mhz in LSB and FSK, but not used by the BM. BM is not used in Rx operation. So disregard these signal other than the low levels you measured cannot be correct if your counter is working properly. I suspect you are not using O-scope properly. Are you using a 10X probe?

What I meant to say is at CA-2 and TP-5 the only frequency and level we care about is in CW and FSK positions of the mode switch in Tx. CA-2 carrier oscillator should be approx 250mv rms @ 8830.70mhz when in CW and FSK mode when flipped to send. This is what you are trying to validate. Measure at TP-5 in FSK as you know it is working. So use it to get your O-scope set up correctly and you can see approx 850mv P-P at 8830.7mhz. Once you can read that on your O-scope now switch to CW mode and flip to send to measure carrier osc signal level at TP-5.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Yes this new format gives me problems as well.

1. You are getting proper dc bias voltage to the BM. You need to confirm you are getting the Carrier Osc signal.

2. You cannot measure any Carrier freq or level at TP-5 in RX for any position of the mode switch. You may read some leakage signals in RX mode but meaningless. The BM is only used for TX and not RX. Only time you can measure any meaningful Carrier Osc frequency or level at TP-5 is in TX with the mode switch in CW or FSK. Carrier in RX mode is applied to another Mixer called the Product Detector and it arrives at IF board on IF-4 C1A terminal. You have separate Carrier Oscillators for RX and TX.

Also, the Car Level Pot has nothing to do with the Carrier Osc levels produced on the CAR Assembly Unit. The Car level pot unbalances the balanced modulator and determines the carrier output level from the BM.

You really need to measure CA-2 produced on the CAR-2 board. If you do not have 300mv of 8830.7mhz at TP-5 in CW mode when you flip to Send then you have to work your way back from TP-5 to CAR-2 board. CA2 can be checked on the 7th terminal up on the white terminal block on the CAR-2 board. On the IF board it comes in on Conn IF-5 pin 13.

At this point you have not confirmed that you have CAR-2 Q1 Oscillator running and available.

3. The DC voltages that you measured at D1 prove that you are getting the turn on voltages for Buffer amp Q2 so if Q1 is oscillating should get CW TX Carrier at CJ-3 and on to the IF board if all connectors are good.

You may have to adjust the frequency and output level but can talk about that later.

Suggest you buy a Freq Counter. Can measure Freq roughly with O-scope. Some measure and display Freq (may or may not do so accurately) and some require using F=1/T and not accurate enough for adjusting the Oscillators in the KW hybrids.

Terry K9TW

Let's try this again. For some reason yahoo has been mangling my posts. This has been a problem ever since they went to this new stupid format they are using.

Measuring at TP-2 the voltage varies from 16 mV to .443V when adjusting the CAR control in both FSK and CW mode. On Conn IF-5 at the CV terminal, the voltage varies from .12V to 8.95V in both FSK and CW mode when adjusting the CAR control.

Also, on the FIX VOX board FIX3-11 is grounded with no key plugged in. Plugging a key in, FIX3-11 follows the key (open key up, grounded key down).

I have cleaned the contacts on the Mode switch and checked for broken wires.

At TP-5 I measure 8.831434 MHz at .64V P-P (on scope) in all positions of the mode switch without the Send switch flipped. When I flip the Send switch the voltage drops to .48V P-P. The CAR control has no affect on the signal level with the Send switch in either position.

I measure 8.97V at the CW terminal on CAR-2 when I flip the Send switch. I measure 8.94V at the anode of D1 and 8.19V at the cathode when the Send switch is flipped.

I have a couple of multimeters, a 150 MHz analog scope, 100 MHz digital scope, W7ZOI power meter, and a KA7EXM power meter. I feel comfortable taking measuremen

In this contest, the first two digits (5, 9) are immaterial). A carryover from older tradition of contest contact acknowledgement. It's the last two digits that are important. Many many amateurs love the competition of weekend contests (great rigs, great antennas, endurance, etc.). A nice change from the typical QSO.

two more questions since I've gotten some more ideas about things that may be causing me problems to look into.
1. Does it hurt to re-neutralize tubes (assuming they were neutralized correctly in the first place)? I don't see any WHEN to neutralize tubes OTHER than when replaced.
2. If instead of "bent fingers" on the band switch there is a "straight finger" on the contact band that i'm having a problem with, besides trying to clean the contact, is there any way of trying to use a needle nose or something (after I discharge the voltage) to re-bend that finger, or am I just going to break it off if I try that? There's noticeable difference when placing a piece of paper under that finger as opposed to the next one which is bent similar to the others.

First, it is good form to sign your posts with your first name and callsign.
You should retune the final slightly when you go form you go from one end of a band to the other. SWR changes when you change frequency away from the antennas resonant point

If the SWR is higher on the low end , it means your longer than optimum, when it is low on the high end it is longer than optimum length.

Subject: [TS-520_820_530_830] ts-520 10 meter question general question

First thank you to everyone who has posted both questions and answers, being a new operator I've already learned a lot from previous messages and files. I'm still learning and very green (i'm not the quickest at dipping and peaking yet or even finding all the knobs) but my question is with a 10 meter dipole I have, I read a higher SWR on the 28.5 band switch settings, and much lower SWR's on the 28 band and 29.1 band. If I understand everything I've learned so far, this is opposite of what I would expect. I.e., I should be reading one low SWR somewhere, and increasingly higher SWR's. Since to me it seems inverted of what is should be, what should I be focusing on? Also possibly related if i'm not consistently doing it, is the need to dip and peak when changing "bands" related to the band switch on the radio or just the general ham band, meaning that you only dip and peak once for 10 meter instead of each of the three 10 meter band switch settings.

45501. TS520s coil cores

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)

Hi does any one know of a source for the cores to fit the following coils please,
The Drive / Oscillator / Antenna / Mixer
This was a second hand purchase that only operates on one band due to most of the above being cracked.
I would like to get the old girl on the air and operating on all bands, any help would be most appreciated.

Peter,

  Finding the proper sized cores will be a great problem. If, the cores are not totally broken,
and can be removed...they can usually be removed and turned end-for-end, as they are "hollow" all the way through. Removing them can present problems in itself. More on that later.....

I do not know of any supplier on your side of the pond..but over here, you can give Bob Mansker an email: ke5ftf@... He has a good supply of stuff for KW hybrids...but this may be a tall order.

      Cheers..............

Brian,

Neutralizing your finals should be done when they are replaced, as you noted. Unless you do a major alignment, or suspect trouble with them(no need to go into that here)...no reason to mess with them.

The "fingers" are made of several metals...and designed to be "springy." First question is:
"why is it bent out in the first place?" Also, WHICH band switch wafer? You can use a tuning tool or, other suitable item, to GENTLY apply pressure to the contact(s)

>two more questions since I've gotten some more ideas about things that may be causing me problems to look into.
>1. Does it hurt to re-neutralize tubes (assuming they were neutralized correctly in the first place)? I don't see any WHEN to neutralize tubes OTHER than when replaced.
>2. If instead of "bent fingers" on the band switch there is a "straight finger" on the contact band that i'm having a problem with, besides trying to clean the contact, is there any way of trying to use a needle nose or something (after I discharge the voltage) to re-bend that finger, or am I just going to break it off if I try that? There's noticeable difference when placing a piece of paper under that finger as opposed to the next one which is bent similar to the others.

Hi Everyone.

Well, I am a contester.

I love to contest, it's a test of radio and operator in the harshest of conditions. And you can work the world in 48 hours. I've worked stations that my friends have spent years trying to get, and I did it in one weekend.

As far as the noise, and complaints, you have to put it into focus, on any given contest weekend, 30 - 40% of the worlds operators will be on the air as compared to only 4 - 5% any other time.

The only reason I am not in this contest, and am instead writing this is because my station is still in boxes from moving to a new house, infact I even forgot the contest was this month until I read this post.

Last CQWW I ran my TS520SE on 80 mtrs as a run station and had a blast, especially when I told people what I was running.

One German operator asked my why I would run such an outmoded rig in a contest, and was surprised when I answered, Because I can.

One of my best memories in a contest is from the early 1990's, I was working Japan on 15 mtrs, hunting and pouncing, when I heard a faint buz off the back of my beam, I switched to a vertical antenna I have and almost fainted when I heard an American operator at Byrd Station Antartica calling CQ, I swung the Yagii around and we chatted for 15 minutes before I put him up on the cluster and lost him in the noise.
His QSL Card is on my wall in my shack today.

So please don't be upset with us contesters, we will be gone by Monday and you can have the airwaves back again.....until the next test.

PS. I also love to DX and rag chew.
One other consideration as well if you please, in an emergancy, when the crap has hit the fan, go to a contest station, it will get the message through.

I mean no disrespect towards anyone who participates in contest.

Although I don't care for nor do I participate in contest, I do believe hams have a right to participate in contest if they so chose to.

Having said that I also believe signal reports should be honest. If band conditions are poor and one station has to ask 4 to 5 times for the callsign of another station, not because of interference or because the other station can't speak properly but rather because of poor band condition, then give an honest report. Too many contest stations seem to be followers which means they simply follow and do what other contest stations do whether it's right or wrong, and that is not what a contest stations should do. Many stations, whether they are participating in a contest or not, rely on an honest report so they can determine how well the band is from their location so why not be honest about the signal report?

Some stations may believe if they waste a few seconds or so giving an honest report that few extra seconds may mean loss of a few contacts. I don't believe that. Just be honest when giving a signal report, it's not going to effect your score nor will it change the outcome of your participation in the contest. It will, however, show that you are being honest.

45509. RE: TS-820 strange transmit problem

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-26 21:32:32 UTC
From: <rcbuckiii@...>
Topic: 45375 Message: 45509

Terry,

These are the readings taken with IF2 connector in all three positions (P-P values):
Position A: D7 cathode: 800mV CW, 800 mV FSK --- D8 cathode: 600mV CW, 400mV FSK
Position B: D7 cathode: 600mV CW, 800 mV FSK --- D8 cathode: 44mV CW, 400 mV FSK
Position C: D7 cathode: 260mV CW, 800 mv FSK --- D8 cathode: 40mV CW, 400 mV FSK
All readings were taken with my scope with the probe in the 10X position to prevent loading of the circuit.

These are the DC readings for D7 and D8 in all three positions (RMS values):
Position A: CW - D7 anode: -3.6V, cathode: 2.0V -- D8 anode: 0V, cathode: 9.0V
Position A: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode 8.5V
Position B: CW - D7 anode: 2.8V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.7V
Position B: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode: 8.5V
Position C: CW - D7 anode: 2.8V, cathode: 2.2V -- D8 anode: 9.3V, cathode: 8.6V
Position C: FSK - D7 anode: 2.7V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.6V

The only position I get output in CW mode is when the connector is in position A.

The CW filter is a TRIO YG-88C and I have re-soldered all connections on the filter.

I meant Cathode voltages but I think you get the idea. Measure the Anode and Cathode to ensure both diodes are being switched on. Should see approx 0.65 vdc drop across D7 and D8 as they are silicon diodes.

Not likely bad but if you need to replace I offer the following:

Should you need a diode do not use a NTE 177 sub. These are 1S1587 fast switching diodes with a fast reverse recovery time of approx 2 ns so I would not use a general purpose silicon diode as NTE sub guide suggests. Can use a NTE 519, but it has a recovery time of approx 70 ns.

I think a 1N914 or 1N4148 would be better choice at 4ns..These are still pretty commonly available.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK I forgot to give you the Anode voltages of D7 and D8 but you can just subtract approx 0.65vdc for the turn on voltage.

280mv P-P is high by my measurements, but if you read close to same in FSK-T then call it good. Certainly better than be too low.

6 mv P-P at output in CW-T is definitely a problem. As I said you can jumper the filter with a .047uf cap and see if you get CW Tx.

Is this the factory YG-88C filter?

I believe it has center frequency of 8830.7 mhz.and bandwidth of 500hz at -6dB.
I have never swept one.

It would not seem likely that you would have bad solder connections if the filter is working in FSK mode. Are you 100% certain you are not using the SSB filter in FSK mode?

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

My voltages at D7 and D8 are virtually identical to yours. I had previously measured the levels at D7 and D8. I measured 280mV P-P where C14 connects to the CW filter and only 6mV P-P out of the filter. But that was before I changed the cable to position A. I will have to move the cable back to C and re-measure tomorrow. I will also pull the IF board out and resolder the CW crystal filter connections. It may be bad solder connections as you suggest.

I just made my first contact in 17 years on 7.020 with W5TZC about 30 mins ago. He gave me a 579 which is pretty good considering my antenna is only 8 feet off the ground. I also still have to address why they final isn't tuning properly on 40 meters. It tuned max power with plate knob pointer sitting on the 5 of 3.5. It dips at 14 on 20 meters.

If I can get the CW filter issue worked out I will go through a complete tuneup of the radio following the service manual procedures.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

It is easy to test CW filter switching diodes D7 and D8. I thought you already did this and reported good?

As previously noted my plug is in C all the way toward the front panel.

Conn IF-2 pins 4 and 5 have approx 12.9vdc on them in Rx and Tx for CW-R, CW-T, FSK-R, and FSK-T.

The cathode of D7 is:
CW-R and FSK-R = 2.90vdc
CW-T and FSK- T = 2.90vdc

The cathode of D8 is : (Note: When you connect voltmeter back ground noise will drop significantly).
CW-R and FSK-R = 10.0vdc
CW-T and FSK-T = 9.80vdc

The reading will be different as the diodes are biased to different current levels. You can see the difference in the supply resistors for each diode.

I have never been able to measure TX level diagram RF voltages accurately using a 1X scope probe. It will pull your ALC indication down from FSD (40 over) to approx 25 over.

You should be able to measure the 8.830mhz TIF signal level at the input and output of the CW Xtal filter. I thought we did this a long time ago?

It is normal for the filters to have an insertion loss. Should have a minimum of approx 25mv rms at D7 input and minimum of approx 19mv rms at D8 output.

Here are my RF level measurements at D7 and D8:

Test conditons: 14.175mhz, Heater on , SG switch off, CW mode, Drive control peaked, Car Pot at 2.5 (for full scale ALC deflection or 40 over)

Boonton 92E (using 10x scope probe very close to same levels)
D7 = 58mv
D8 = 25mv

You can jumper across your CW filter with a couple of mini-grabber test leads with a 0.047uf capacitor in series.

Could have good switching diodes and good filter but bad solder connections at the filter?

Terry K9TW.

Terry,

I have made a discovery that will probably tell us where the actual problem is. I was googling how to replace CW filter and found this link:
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2

So I downloaded the operators manual and looked at page 34. Kenwood is perfectly clear about this. If the plug is in position A, the CW filter is bypassed.

I put the plug in position A and can tune to full power out in CW mode. If I place the plug in position B or C I get no power out when in CW mode.

Does this indicate a bad CW filter? The filter works fine in receive mode. The only thing I have noticed is that if I switch from USB to CW the signal drops 1 S-unit when peaked for max signal in both modes.

Ray AB7HE

Terry,

At this point I am using my scope with 1 meg input. If is become suspicious of the reading I switch the 10X on and take the reading that way.

An immediate problem I see is I only have 10mV P-P at the drain of Q1 in FSK mode and 0 output in CW mode. The diagram says there should be 250 mV rms there. If I pull the CW filter out of the radio, how does the CW transmit work? Does the signal then go through the

USB filter or do I need to install a jumper where the CW filter was?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Yes they are RMS.

I take them at around 14.175 to 14.200 mhz with the Car Level pot advanced to the point that with the Drive Control adjusted for a peak in ALC indication at panel meter full scale deflection. Then switch to CW mode and load to approx 100 watts out and turn off SG switch. Leave Car Level and Drive control alone.

Measured values will vary depending on what test instrument you are using, length of any test jumper leads used to access the test points, line voltage.

For example 8.830mhz TIF output at the IF board and input at the RF board is shown as 0.038v. This is 38.0 mv rms rf volts or 38 x 2.828 = 107 mv P-P. So if you have approx 100mv P-P TIF you are good.

Output of the TX Mixer is 1.4v rms or 4.0v P-P. This RF drive level is now 14.175 mhz.

If you plan on doing a lot of this work suggest you invest in a RF Millivolt meter. I use a Boonton 92E. I find it loads the circuits less and just easier and faster to use.

Of coures once you get to the 1.4 volts at output of the TX Mixer the old fashioned RF probe and VTVM works great. Just have to use multi-diode probe at plate of Driver tube and control grids of the Finals. I used a Heath 309C and PK-3 probes and a IM-18 VTVM for years and still have them for fall back.

Terry,

Are the transmit levels on page 42 of the service manual correct? Are those RMS values?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Thanks Terry. I have been talking to you since you have been helping. I don't know what made me put Dave on the last message (old age maybe).

I decided to start over from the beginning and go stage by stage this afternoon. This is what I did:
(All measurements taken with Send switch operated and Mode switch in CW position. Also, the measurements are the same in both CW and FSK modes.)

I suspected D1 or L1 was bad on the CAR-II board was bad but that is not the case. I have 720mV on CA2 leaving the CAR-II board in both CW and FSK send modes. I also have 720mV P-P on CA2 (IF5-13) on the IF board. I have 100mV P-P at the coax that connects to C92 on the IF board. On the other end of that coax where it connects to the top of T4 on the IF board I also have 100mV P-P. I would have thought the signal out of Q18 would have been stronger

but maybe not.

I have 340mV at the junction of the cathode of D7 and C14 on the IF board. I have 280mV on the side of C14 where it feeds the CW filter. The signal going into the filter measures 8.830755 MHz. I only have 6mV P-P coming out of the crystal filter. Is the crystal filter used for transmit?

I connected the antenna to the radio and 20 meters is open. Tuning in CW signals in USB mode and switching to CW mode drops the signal by about 1 S-Unit when the signal is peaked for max signal in both modes.

Where do I go from here?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Are you talking Dave or Terry ? If someone is helping you off list I can back away as I have a pretty full plate right now.

I am not clear where you are measuring this 40mv P-P signal at?

Before I go I will mention that it is normal to not have a clean sine wave at TIF. It does have harmonic content and it is as you say due to LO mixing action. In this case it is coming from the VCO signal feeding back from the TX Mixer on RF board to the IF board.

This is easy to confirm with a TS-830 as you can easily unplug the VCO cable from the PLL board and the TIF signal will then be a nice clean 8.830mhz sine wave.

Dont worry about the complex waveform. Should still be able to get a reasonably close TIF measurement. It may not match exactly the levels on the TX Level Diagram,but you can compare it to the level you get with FSK carrier oscillator.

I dont use a O-scope to run TX Level diagrams once I get to the output of the TIF amp. I use a Boonton RF Millivolt meter and measure levels in rms and the "dirty" TIF signal presents no problem.

I have a new digital O-scope and it has a variety of digital filters. If I set it for a LP filter with a roll off frequency of 10mhz I can get a pretty clean 8.830 TIF sine wave display.

I dont know the Tek 2445 capability in this regard.

One final reminder is that good TIF signal level of approx 38mv rms or 107mv P-P is based on the premise that you accurately measured CA2 at the iF board of approx 300mv rms or 850mv P-P.

If that signal is not there then you would need to repeat the testing I asked you to do at the Carrier Osc board to confirm the 9vdc CW diode switching voltage is available at D1 and Q2 Buffer amp is being turned on.

I have been providing direction based on your reporting back that you have good CA-2 at Carrier board and good CA-2 at TP-5 on IF board.

If good Level at TP-5 then should have proper level at the wiper of VR-5 on the Balanced Mod. As we have discussed. No dc bias from CV and no Carrier at wiper of VR-5 then no output from the Bal Modulator.

I am pretty confident that you do have proper bias voltage from CCW to full CW on the Car Pot, but I am not certain yet that you have proper carrier output from the BM in CW mode.

Good luck.

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Dave,

I have VFO set to 14.175. With Car pot at 1200, in CW mode I get 40mV P-P in RX mode. When I flip the Send switch, the signal stays at 40 mV but it is no longer a sine wave. It is some kind of more or less sine wave with a lot of noise on it. With the Car pot at max, the noisy sinewave increases to 60 mV P-P in Send mode.

In FSK mode with Car at 1200 I get 250mV P-P in Send mode. With Car at Max I get 800 mV P-P in Send mode.

At Conn RF1-10 I get 140mV P-P in CW Send mode. I get 800mV P-P in FSK Send mode.

At the mixer output (Q1 and Q8 side of C8) I get 100 mV P-P in CW Send mode. I get 1V P-P in FSK Send mode. The signal at that point is not a sinewave but seems to have multiple signals. Probably some LO feedthrough on the mixer. The frequency counter agrees with the Kendwood readout as 14.1748 MHz.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Sorry about Q10 vs Q18. My fingers work better than what is left of my brain.

The 3 conductor plug should be positioned in forward position toward the front panel.

One thing we did not talk about is whereiyou should have the Car Level Pot set to take these measurements.

The TX Level Diagram is shown in the Service Manual. These levels were taken by Kenwood by loading the rig to approx 100 watts out at 14.175mhz and then turn the SG switch off and leave Car pot alone and Drive control alone.

Since you have no RF output in CW mode I suggest you do this for remainder of the readings:

1. VFO 14.175
2. Peak the Drive Control on receiver noise or the marker signal
3. Car Level Pot 1200
4. Heater on
5. SG switch off
6. Flip to Send to take RF drive levels

So the differences in voltages may be due to where we each have our Car Level pot set at.

Suggest you measure the voltage and frequency of the TIF signal at IF-3 Pin 2 one more time and it should be approx 250mv rms or 700mv P-P @ 8830.7mhz.

If you have close to this time to move on to the RF board. I must say this is getting a little odd as you have good output ini SSB and FSK which tells us you have good TIF level and the TX Mixer on RF Board is working which means you have good VCO (LO to the mixer).

Are you 100% certain you have no CW RF output on all bands? If so, then proceed on to the RF board with Heaters On and SG off and rig peaked as noted above.

You should have close to the values noted on the TX Level Diagram. At Conn RF-1 Pin 10 the 8.830 TIF signal level is approx 38mv rms or 108 P-P.

At output of TX Mixer should have approx 1.5v rms or 4.2v P-P rf drive at MD. At MD frequency will now be 14.175mhz transmit frequency.

If you have no RF drive or very weak at MD then need to measure the VCO level and frequency at RF-1 pin 4 and on board at TP-1. Should be close to 1.0v rms level. If no VCO try on other bands.

We are making good progress. Your Tek 2445 is perfect scope for KW Hybrid work and you apparently know how to use it and can read a schematic and can locate points on these high density boards to take measurements. This really helps.

Based on your report of no RF output in CW mode I would have thought we would have found no TIF sig at output of the IF board. TIF is not band specific and often is caused by no output from the Bal Modulator, This is why I had you start by testing for bias voltage and LO signal available. Never expected that we would be at the RF board and TX Mixer based on good RF output on other modes.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I read a little over 700mV at the drain of Q18 (actually the backside of C92 feeding the coax). I think you meant Q18 instead of Q10.

D7 and D8 are the CW switching diodes. With the mode switch in CW position, I have 2.98 volts on the anode of D7 and 2.34 volts on the cathode. I have 10.0 volts on the anode of D8 and 9.40 volts on the cathode. These voltages are there in both RX and TX, just a few 10ths of a volt lower in TX mode.

Can you confirm how the 3 pin cable ofr IF2 is supposed to plug in? It only has 3 wires but there are 5 pins on the IF board at that point. According to the chassis wiring diagram, only the first 3 pins are used as they come from S6-1.

I don't think there is anything wrong with the CW filter and the switching diodes as the CW filter works fine in RX mode.

I have 400mV P-P on Gate 1 of Q1 instead of the 160mV when flipping Send. I also have 2400mV P-P on the drain instead of 1000mV when flipping Send.

TIF signal on Conn IF-3 is 400mV P-P and the sine wave isn't quiet as clean there as it is on the drain of Q1.

Hopefully we are making progress.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Good job. Much better.

If I understand your chart you are telling me that you have approx 640mv P-P @ 8.83077 at TP-5 in CW mode with rig flipped to Send (heaters off and SG switch off). 900mv P-P is attainable by adjusting T1 on CAR-2 board, but can do later unless you want to peak it now. 640mv will work for testing.

If this is true then you have confirmed that you have the two things you need at the Balanced Mod to produce RF output from it in CW mode. 1. Offset bias voltage and 2. Proper Carrier freq and level.

From the BM output the CW signal is routed to the Crystal IF Filter and then to Q1 the Transmit IF Amp or TIF amp. TIF signal leaves the IF board and is routed to the RF board to the TX Mixer where it is mixed with VCO to produce the actual transmit rf drive signal. No TIF signal and there will be no RF drive and no RF output. Also no VCO or low VCO level and no rf drive. Lets validate that we have TIF signal in CW mode first.

Unfortunately KW didnt provide a nice test point at the output of the Balanced Mod to measure the DSBSC signal in SSB mode or the Carrier in CW mode. However, you can get on the Drain of Q10 with a hat pin or floral arrangement pin and mini-grabber test lead. If you locate the BM ring diodes D26-D29 and then output Xfmr T10 you will see Q10. It is a metal can dual gate mosfet. Looking down on the can the Drain is the upper right lead. You should read approx 800mv P-P here. This signal is routed to the Xtal filter thru switcing diodes.

Do you have the CW filter installed. It is rare but could have a bad filter. More common to have a bad switching diode.

After signal passes thru the Xtal filter it is applied to Gate 1 of TIF amp Q1. It is also a metal can dual gate mosfet and sits outside and almost between the two filters at the inboard end. Looking down on Q1 Gate 1 is at 1200. Should have approx 160mv P-P here. The Drain is at 0600 and should have approx 1000mv P-P. TIF output is on Conn IF-3 Pin 2 and should have approx 850mv P-P here. You can jump right to measuring TIF output if you want and if good then off to the RF board.

We know that you have TIF output in FSK mode as you reported good RF output in that mode. I dont kow if you keyed rig in FSK and noted the 170hz shift or not, but not important right now. Also, you should have noted that the RF output in FSK is lower as the 820 lowers the Finals Screen Grid voltage in FSK mode so the tubes plate dissipation is not exceeded in this high duty cycle mode.

That should be enough for now.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

This is what I am seeing:
TP-5 and CJ3-CA2 have the same levels in CW and FSK modes: 820mV P-P in RX mode. Flipping Send switch the level drops to 640mV P-P. I have a Tektronix 2445 Scope and have the probe in 10X to prevent loading the circuit.

Frequencies measured at CJ3-CA2:
RX mode FSK - 8.828414 - TX mode FSK 8.830620
RX mode LSB - 8.828414 - TX mode LSB 8.828579
RX mode USB - 8.831460 - TX mode USB 8.831625
RX mode CW - 8.831460 - TX mode CW 8.830777

Frequencies measured at TP-5:
RX mode FSK - 8.828410 - TX mode FSK 8.830616
RX mode LSB - 8.828410 - TX mode LSB 8.828575
RX mode USB - 8.831450 - TX mode USB 8.831622
RX mode CW - 8.831446 - TX mode CW 8.830773

I am using a Simpson 710 Frequency counter. Specs say 1 Meg input shunted by 30 pF. The slight differences in frequency readings between CJ3-CA2 and TP-5 is probably due to the cable capacitance of the cable between IF5-13 and CJ3-CA2.

I have been taking all of these measurements with the SG switch turned off and the heater switch turned off.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

I mis-spoke in Item 2 when I said you cant measure carrier at TP-5 in Rx in any of the mode switch positions. There will be legitimate carrier but not of interest.

There will be Carrier at CA-2 and TP-5 in Rx in all positions of the mode switch that you should see, but it is meaningless for CW Tx operation. It was not correct for me to label it as "Leakage" signals.

It is there by design but not for Rx or Tx operation. CA-1 Carrier Osc signals are coupled to the CAR-2 board to amp Q3 and then on to TP-5 at IF board and then sampled and sent to the CCR lead to provide carrier oscillator signals for the Counter Mixer Board. So the carrier osc signals you were measuring at each position of the mode switch in Rx are there by design to feed the counter, but of no interest to us as not utilized for the BM and CW transmit.

So you will see approx 250mv rms at 8831.50 mhz in CW and LSB and 250mv at 8828.5mhz in LSB and FSK, but not used by the BM. BM is not used in Rx operation. So disregard these signal other than the low levels you measured cannot be correct if your counter is working properly. I suspect you are not using O-scope properly. Are you using a 10X probe?

What I meant to say is at CA-2 and TP-5 the only frequency and level we care about is in CW and FSK positions of the mode switch in Tx. CA-2 carrier oscillator should be approx 250mv rms @ 8830.70mhz when in CW and FSK mode when flipped to send. This is what you are trying

to validate. Measure at TP-5 in FSK as you know it is working. So use it to get your O-scope set up correctly and you can see approx 850mv P-P at 8830.7mhz. Once you can read that on your O-scope now switch to CW mode and flip to send to measure carrier osc signal level at TP-5.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Yes this new format gives me problems as well.

1. You are getting proper dc bias voltage to the BM. You need to confirm you are getting the Carrier Osc signal.

2. You cannot measure any Carrier freq or level at TP-5 in RX for any position of the mode switch. You may read some leakage signals in RX mode but meaningless. The BM is only used for TX and not RX. Only time you can measure any meaningful Carrier Osc frequency or level at TP-5 is in TX with the mode switch in CW or FSK. Carrier in RX mode is applied to another Mixer called the Product Detector and it arrives at IF board on IF-4 C1A terminal. You have separate Carrier Oscillators for RX and TX.

Also, the Car Level Pot has nothing to do with the Carrier Osc levels produced on the CAR Assembly Unit. The Car level pot unbalances the balanced modulator and determines the carrier output level from the BM.

You really need to measure CA-2 produced on the CAR-2 board. If you do not have 300mv of 8830.7mhz at TP-5 in CW mode when you flip to Send then you have to work your way back from TP-5 to CAR-2 board. CA2 can be checked on the 7th terminal up on the white terminal block on the CAR-2 board. On the IF board it comes in on Conn IF-5 pin 13.

At this point you have not confirmed that you have CAR-2 Q1 Oscillator running and available.

3. The DC voltages that you measured at D1 prove that you are getting the turn on voltages for Buffer amp Q2 so if Q1 is oscillating should get CW TX Carrier at CJ-3 and on to the IF board if all connectors are good.

You may have to adjust the frequency and output level but can talk about that later.

How many times have I heard, " Station calling, You're 59 but repeat everything" ??

On Saturday, October 26, 2013 3:35 PM, Mike <w5rkl@...> wrote:

I mean no disrespect towards anyone who participates in contest.

Although I don't care for nor do I participate in contest, I do believe hams have a right to participate in contest if they so chose to.

Having said that I also believe signal reports should be honest. If band conditions are poor and one station has to ask 4 to 5 times for the callsign of another station, not because of interference or because the other station can't speak properly but rather because of poor band condition, then give an honest report. Too many contest stations seem to be followers which means they simply follow and do what other contest stations do whether it's right or wrong, and that is not what a contest stations should do. Many stations, whether they are participating in a contest or not, rely on an honest report so they can determine how well the band is from their location so why not be honest about the signal report?

Some stations may believe if they waste a few seconds or so giving an honest report that few extra seconds may mean loss of a few contacts. I don't believe that. Just be honest when giving a signal report, it's not going to effect your score nor will it change the outcome of your participation in the contest. It will, however, show that you are being honest.

Greetings Group!

This must be a banner month, so many new members! I am glad to see that there is still a "spark"
out there for these fine old rigs!

Recently, there has been an increase of disrespect, inappropriate comments,
and other "comments" directed to members of this group. I understand that there
will be "disagreements" about certain troubleshooting procedures/findings, but
do not get "pissy" about it. We all ALL here for the same reason. If for some reason,
you can not, or will not, go by these simple rules...just UNSUSCRIBE! Or, the

moderator(s) or co-owner(s) can always put you on "moderate" and review any/all
messages you want to post, and either approve or deny them...or just ban the
offending person(s).

That's all for now...back to our regular programing.....

As I said earlier, the signal report is immaterial. 99.99% of the contest operators don't really care. The name of the game is to amass as many contacts as possible. The only data that's important is call, and with this contest, the CQ Zone Number. With computer logging programs, one less variable to worry about (R-S) is good. Everyone is 5-9. There's been a push for years the rid the contests of R-S reports on HF contests, but some traditions are hard to break. On VHF contests, all we give is a grid square for the contest exchange.

On Sat, 26 Oct 2013 14:35:03 -0500 Mike <w5rkl@...> writes:

I mean no disrespect towards anyone who participates in contest.

Although I don't care for nor do I participate in contest, I do believe hams have a right to participate in contest if they so chose to.

Having said that I also believe signal reports should be honest. If band conditions are poor and one station has to ask 4 to 5 times for the callsign of another station, not because of interference or because the other station can't speak properly but rather because of poor band condition, then give an honest report. Too many contest stations seem to be followers which means they simply follow and do what other contest stations do whether it's right or wrong, and that is not what a contest stations should do. Many stations, whether they are participating in a contest or not, rely on an honest report so they can determine how well the band is from their location so why not be honest about the signal report?

Some stations may believe if they waste a few seconds or so giving an honest report that few extra seconds may mean loss of a few contacts. I don't believe that. Just be honest when giving a signal report, it's not going to effect your score nor will it change the outcome of your participation in the contest. It will, however, show that you are being honest.

Hi Everyone.

Well, I am a contester.

I love to contest, it's a test of radio and operator in the harshest of conditions. And you can work the world in 48 hours. I've worked stations

that my friends have spent years trying to get, and I did it in one weekend.

As far as the noise, and complaints, you have to put it into focus, on any given contest weekend, 30 - 40% of the worlds operators will be on the air as compared to only 4 - 5% any other time.

The only reason I am not in this contest, and am instead writing this is because my station is still in boxes from moving to a new house, infact I even forgot the contest was this month until I read this post.

Last CQWW I ran my TS520SE on 80 mtrs as a run station and had a blast, especially when I told people what I was running.

One German operator asked my why I would run such an outmoded rig in a contest, and was surprised when I answered, Because I can.

One of my best memories in a contest is from the early 1990's, I was working Japan on 15 mtrs, hunting and pouncing, when I heard a faint buz off the back of my beam, I switched to a vertical antenna I have and almost fainted when I heard an American operator at Byrd Station Antartica calling CQ, I swung the Yagii around and we chatted for 15 minutes before I put him up on the cluster and lost him in the noise. His QSL Card is on my wall in my shack today.

So please don't be upset with us contesters, we will be gone by Monday and you can have the airwaves back again.....until the next test.

PS. I also love to DX and rag chew.
One other consideration as well if you please, in an emergancy, when the crap has hit the fan, go to a contest station, it will get the message through.

Terry, with a .047 capacitor across the CW filter, I get full output in CW mode regardless of what position the IF2 connector is in.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

These are the readings taken with IF2 connector in all three positions (P-P values):
Position A: D7 cathode: 800mV CW, 800 mV FSK --- D8 cathode: 600mV CW, 400mV FSK
Position B: D7 cathode: 600mV CW, 800 mV FSK --- D8 cathode: 44mV CW, 400 mV FSK
Position C: D7 cathode: 260mV CW, 800 mv FSK --- D8 cathode: 40mV CW, 400 mV FSK
All readings were taken with my scope with the probe in the 10X position to prevent loading of the circuit.

These are the DC readings for D7 and D8 in all three positions (RMS values):
Position A: CW - D7 anode: -3.6V, cathode: 2.0V -- D8 anode: 0V, cathode: 9.0V
Position A: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode 8.5V
Position B: CW - D7 anode: 2.8V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.7V
Position B: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode: 8.5V
Position C: CW - D7 anode: 2.8V, cathode: 2.2V -- D8 anode: 9.3V, cathode: 8.6V
Position C: FSK - D7 anode: 2.7V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.6V

The only position I get output in CW mode is when the connector is in position A.

The CW filter is a TRIO YG-88C and I have re-soldered all connections on the filter.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

I meant Cathode voltages but I think you get the idea. Measure the Anode and Cathode to ensure both diodes are being switched on. Should see approx 0.65 vdc drop across D7 and D8 as they are silicon diodes.

Not likely bad but if you need to replace I offer the following:

Should you need a diode do not use a NTE 177 sub. These are 1S1587 fast switching diodes with a fast reverse recovery time of approx 2 ns so I would not use a general purpose silicon diode as NTE sub guide suggests. Can use a NTE 519, but it has a recovery time of approx 70 ns.

I think a 1N914 or 1N4148 would be better choice at 4ns..These are still pretty commonly available.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK I forgot to give you the Anode voltages of D7 and D8 but you can just subtract approx 0.65vdc for the turn on voltage.

280mv P-P is high by my measurements, but if you read close to same in FSK-T then call it good. Certainly better than be too low.

6 mv P-P at output in CW-T is definitely a problem. As I said you can jumper the filter with a .047uf cap and see if you get CW Tx.

Is this the factory YG-88C filter?

I believe it has center frequency of 8830.7 mhz.and bandwidth of 500hz at -6dB.
I have never swept one.

It would not seem likely that you would have bad solder connections if the filter is working in FSK mode. Are you 100% certain you are not using the SSB filter in FSK mode?

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

My voltages at D7 and D8 are virtually identical to yours. I had previously measured the levels at D7 and D8. I measured 280mV P-P where C14 connects to the CW filter and only 6mV P-P out of the filter. But that was before I changed the cable to position A. I will have to move the cable back to C and re-measure tomorrow. I will also pull the IF board out and resolder the CW crystal filter connections. It may be bad solder connections as you suggest.

I just made my first contact in 17 years on 7.020 with W5TZC about 30 mins ago. He gave me a 579 which is pretty good considering my antenna is only 8 feet off the ground. I also still have to address why they final isn't tuning properly on 40 meters. It tuned max power with plate knob pointer sitting on the 5 of 3.5. It dips at 14 on 20 meters.

If I can get the CW filter issue worked out I will go through a complete tuneup of the radio following the service manual procedures.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

It is easy to test CW filter switching diodes D7 and D8. I thought you already did this and reported good?

As previously noted my plug is in C all the way toward the front panel.

Conn IF-2 pins 4 and 5 have approx 12.9vdc on them in Rx and Tx for CW-R, CW-T, FSK-R, and FSK-T.

The cathode of D7 is:
CW-R and FSK-R = 2.90vdc
CW-T and FSK- T = 2.90vdc

The cathode of D8 is : (Note: When you connect voltmeter back ground noise will drop significantly).
CW-R and FSK-R = 10.0vdc
CW-T and FSK-T = 9.80vdc

The reading will be different as the diodes are biased to different current levels. You can see the difference in the supply resistors for each diode.

I have never been able to measure TX level diagram RF voltages accurately using a 1X scope probe. It will pull your ALC indication down from FSD (40 over) to approx 25 over.

You should be able to measure the 8.830mhz TIF signal level at the input and output of the CW Xtal filter. I thought we did this a long time ago?

It is normal for the filters to have an insertion loss. Should have a minimum of approx 25mv rms at D7 input and minimum of approx 19mv rms at D8 output.

Here are my RF level measurements at D7 and D8:

Test conditons: 14.175mhz, Heater on , SG switch off, CW mode, Drive control peaked, Car Pot at 2.5 (for full scale ALC deflection or 40 over)

Boonton 92E (using 10x scope probe very close to same levels)
D7 = 58mv
D8 = 25mv

You can jumper across your CW filter with a couple of mini-grabber test leads with a 0.047uf capacitor in series.

Could have good switching diodes and good filter but bad solder connections at the filter?

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I have made a discovery that will probably tell us where the actual problem is. I was googling how to replace CW filter and found this link:
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2

So I downloaded the operators manual and looked at page 34. Kenwood is perfectly clear about this. If the plug is in position A, the CW filter is bypassed.

I put the plug in position A and can tune to full power out in CW mode. If I place the plug in position B or C I get no power out when in CW mode.

Does this indicate a bad CW filter? The filter works fine in receive mode. The only thing I have noticed is that if I switch from USB to CW the signal drops 1 S-unit when peaked for max signal in both modes.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

At this point I am using my scope with 1 meg input. If is become suspicious of the reading I switch the 10X on and take the reading that way.

An immediate problem I see is I only have 10mV P-P at the drain of Q1 in FSK mode and 0 output in CW mode. The diagram says there should be 250 mV rms there. If I pull the CW filter out of the radio, how does the CW transmit work? Does the signal then go through the USB filter or do I need to install a jumper where the CW filter was?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Yes they are RMS.

I take them at around 14.175 to 14.200 mhz with the Car Level pot advanced to the point that with the Drive Control adjusted for a peak in ALC indication at panel meter full scale deflection. Then switch to CW mode and load to approx 100 watts out and turn off SG switch. Leave Car Level and Drive control alone.

Measured values will vary depending on what test instrument you are using, length of any test jumper leads used to access the test points, line voltage.

For example 8.830mhz TIF output at the IF board and input at the RF board is shown as 0.038v. This is 38.0 mv rms rf volts or 38 x 2.828 = 107 mv P-P. So if you have approx 100mv P-P TIF you are good.

Output of the TX Mixer is 1.4v rms or 4.0v P-P. This RF drive level is now 14.175 mhz.

If you plan on doing a lot of this work suggest you invest in a RF Millivolt meter. I use a Boonton 92E. I find it loads the circuits less and just easier and faster to use.

Of coures once you get to the 1.4 volts at output of the TX Mixer the old fashioned RF probe and VTVM works great. Just have to use multi-diode probe at plate of Driver tube and control grids of the Finals. I used a Heath 309C and PK-3 probes and a IM-18 VTVM for years and still have them for fall back.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

Are the transmit levels on page 42 of the service manual correct? Are those RMS values?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Thanks Terry. I have been talking to you since you have been helping. I don't know what made me put Dave on the last message (old age maybe).

I decided to start over from the beginning and go stage by stage this afternoon. This is what I did:
(All measurements taken with Send switch operated and Mode switch in CW position. Also, the

measurements are the same in both CW and FSK modes.)

I suspected D1 or L1 was bad on the CAR-II board was bad but that is not the case. I have 720mV on CA2 leaving the CAR-II board in both CW and FSK send modes. I also have 720mV P-P on CA2 (IF5-13) on the IF board. I have 100mV P-P at the coax that connects to C92 on the IF board. On the other end of that coax where it connects to the top of T4 on the IF board I also have 100mV P-P. I would have thought the signal out of Q18 would have been stronger but maybe not.

I have 340mV at the junction of the cathode of D7 and C14 on the IF board. I have 280mV on the side of C14 where it feeds the CW filter. The signal going into the filter measures 8.830755 MHz. I only have 6mV P-P coming out of the crystal filter. Is the crystal filter used for transmit?

I connected the antenna to the radio and 20 meters is open. Tuning in CW signals in USB mode and switching to CW mode drops the signal by about 1 S-Unit when the signal is peaked for max signal in both modes.

Where do I go from here?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Are you talking Dave or Terry ? If someone is helping you off list I can back away as I have a pretty full plate right now.

I am not clear where you are measuring this 40mv P-P signal at?

Before I go I will mention that it is normal to not have a clean sine wave at TIF. It does have harmonic content and it is as you say due to LO mixing action. In this case it is coming from the VCO signal feeding back from the TX Mixer on RF board to the IF board.

This is easy to confirm with a TS-830 as you can easily unplug the VCO cable from the PLL board and the TIF signal will then be a nice clean 8.830mhz sine wave.

Dont worry about the complex waveform. Should still be able to get a reasonably close TIF measurement. It may not match exactly the levels on the TX Level Diagram,but you can compare it to the level you get with FSK carrier oscillator.

I dont use a O-scope to run TX Level diagrams once I get to the output of the TIF amp. I use a Boonton RF Millivolt meter and measure levels in rms and the "dirty" TIF signal presents no problem.

I have a new digital O-scope and it has a variety of digital filters. If I set it for a LP filter with a roll off frequency of 10mhz I can get a pretty clean 8.830 TIF sine wave display.

I dont know the Tek 2445 capability in this regard.

One final reminder is that good TIF signal level of approx 38mv rms or 107mv P-P is based on the premise that you accurately measured CA2 at the iF board of approx 300mv rms or 850mv P-P.

If that signal is not there then you would need to repeat the testing I asked you to do at the Carrier Osc board to confirm the 9vdc CW diode switching voltage is available at D1 and Q2 Buffer amp is being turned on.

I have been providing direction based on your reporting back that you have good CA-2 at Carrier board and good CA-2 at TP-5 on IF board.

If good Level at TP-5 then should have proper level at the wiper of VR-5 on the Balanced Mod. As we have discussed. No dc bias from CV and no Carrier at wiper of VR-5 then no output from the Bal Modulator.

I am pretty confident that you do have proper bias voltage from CCW to full CW on the Car Pot, but I am not certain yet that you have proper carrier output from the BM in CW mode.

Good luck.

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Dave,

I have VFO set to 14.175. With Car pot at 1200, in CW mode I get 40mV P-P in RX mode. When I flip the Send switch, the signal stays at 40 mV but it is no longer a sine wave. It is some kind of more or less sine wave with a lot of noise on it. With the Car pot at max, the noisy sinewave increases to 60 mV P-P in Send mode.

In FSK mode with Car at 1200 I get 250mV P-P in Send mode. With Car at Max I get 800 mV P-P in Send mode.

At Conn RF1-10 I get 140mV P-P in CW Send mode. I get 800mV P-P in FSK Send mode.

At the mixer output (Q1 and Q8 side of C8) I get 100 mV P-P in CW Send mode. I get 1V P-P in FSK Send mode. The signal at that point is not a sinewave but seems to have multiple signals. Probably some LO feedthrough on the mixer. The frequency counter agrees with the Kendwood readout as 14.1748 MHz.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Sorry about Q10 vs Q18. My fingers work better than what is left of my brain.

The 3 conductor plug should be positioned in forward position toward the front panel.

One thing we did not talk about is whereiyou should have the Car Level Pot set to take these measurements.

The TX Level Diagram is shown in the Service Manual. These levels were taken by Kenwood by loading the rig to approx 100 watts out at 14.175mhz and then turn the SG switch off and leave Car pot alone and Drive control alone.

Since you have no RF output in CW mode I suggest you do this for remainder of the readings:

1. VFO 14.175
2. Peak the Drive Control on receiver noise or the marker signal

3. Car Level Pot 1200
4. Heater on
5. SG switch off
6. Flip to Send to take RF drive levels

So the differences in voltages may be due to where we each have our Car Level pot set at.

Suggest you measure the voltage and frequency of the TIF signal at IF-3 Pin 2 one more time and it should be approx 250mv rms or 700mv P-P @ 8830.7mhz.

If you have close to this time to move on to the RF board. I must say this is getting a little odd as you have good output ini SSB and FSK which tells us you have good TIF level and the TX Mixer on RF Board is working which means you have good VCO (LO to the mixer).

Are you 100% certain you have no CW RF output on all bands? If so, then proceed on to the RF board with Heaters On and SG off and rig peaked as noted above.

You should have close to the values noted on the TX Level Diagram. At Conn RF-1 Pin 10 the 8.830 TIF signal level is approx 38mv rms or 108 P-P.

At output of TX Mixer should have approx 1.5v rms or 4.2v P-P rf drive at MD. At MD frequency will now be 14.175mhz transmit frequency.

If you have no RF drive or very weak at MD then need to measure the VCO level and frequency at RF-1 pin 4 and on board at TP-1. Should be close to 1.0v rms level. If no VCO try on other bands.

We are making good progress. Your Tek 2445 is perfect scope for KW Hybrid work and you apparently know how to use it and can read a schematic and can locate points on these high density boards to take measurements. This really helps.

Based on your report of no RF output in CW mode I would have thought we would have found no TIF sig at output of the IF board. TIF is not band specific and often is caused by no output from the Bal Modulator, This is why I had you start by testing for bias voltage and LO signal available. Never expected that we would be at the RF board and TX Mixer based on good RF output on other modes.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I read a little over 700mV at the drain of Q18 (actually the backside of C92 feeding the coax). I think you meant Q18 instead of Q10.

D7 and D8 are the CW switching diodes. With the mode switch in CW position, I have 2.98 volts on the anode of D7 and 2.34 volts on the cathode. I have 10.0 volts on the anode of D8 and 9.40 volts on the cathode. These voltages are there in both RX and TX, just a few 10ths of a volt lower in TX mode.

Can you confirm how the 3 pin cable ofr IF2 is supposed to plug in? It only has 3 wires but there are 5 pins on the IF board at that point. According to the chassis wiring diagram, only the first 3 pins are used as they come from S6-1.

I don't think there is anything wrong with the CW filter and the switching diodes as the CW filter works fine in RX mode.

I have 400mV P-P on Gate 1 of Q1 instead of the 160mV when flipping Send. I also have 2400mV P-P on the drain instead of 1000mV when flipping Send.

TIF signal on Conn IF-3 is 400mV P-P and the sine wave isn't quiet as clean there as it is on the drain of Q1.

Hopefully we are making progress.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Good job. Much better.

If I understand your chart you are telling me that you have approx 640mv P-P @ 8.83077 at TP-5 in CW mode with rig flipped to Send (heaters off and SG switch off). 900mv P-P is attainable by adjusting T1 on CAR-2 board, but can do later unless you want to peak it now. 640mv will work for testing.

If this is true then you have confirmed that you have the two things you need at the Balanced Mod to produce RF output from it in CW mode. 1. Offset bias voltage and 2. Proper Carrier freq and level.

From the BM output the CW signal is routed to the Crystal IF Filter and then to Q1 the Transmit IF Amp or TIF amp. TIF signal leaves the IF board and is routed to the RF board to the TX Mixer where it is mixed with VCO to produce the actual transmit rf drive signal. No TIF signal and there will be no RF drive and no RF output. Also no VCO or low VCO level and no rf drive. Lets validate that we have TIF signal in CW mode first.

Unfortunately KW didnt provide a nice test point at the output of the Balanced Mod to measure the DSBSC signal in SSB mode or the Carrier in CW mode. However, you can get on the Drain of Q10 with a hat pin or floral arrangement pin and mini-grabber test lead. If you locate the BM ring diodes D26-D29 and then output Xfmr T10 you will see Q10. It is a metal can dual gate mosfet. Looking down on the can the Drain is the upper right lead. You should read approx 800mv P-P here. This signal is routed to the Xtal filter thru switcing diodes.

Do you have the CW filter installed. It is rare but could have a bad filter. More common to have a bad switching diode.

After signal passes thru the Xtal filter it is applied to Gate 1 of TIF amp Q1. It is also a metal can dual gate mosfet and sits outside and almost between the two filters at the inboard end. Looking down on Q1 Gate 1 is at 1200. Should have approx 160mv P-P here. The Drain is at 0600 and should have approx 1000mv P-P. TIF output is on Conn IF-3 Pin 2 and should have approx 850mv P-P here. You can jump right to measuring TIF output if you want and if good then off to the RF board.

We know that you have TIF output in FSK mode as you reported good RF output in that mode. I dont kow if you keyed rig in FSK and noted the 170hz shift or not, but not important right now. Also, you should have noted that the RF output in FSK is lower as the 820 lowers the Finals Screen Grid voltage in FSK mode so the tubes plate dissipation is not exceeded in

this high duty cycle mode.

That should be enough for now.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

This is what I am seeing:
TP-5 and CJ3-CA2 have the same levels in CW and FSK modes: 820mV P-P in RX mode. Flipping Send switch the level drops to 640mV P-P. I have a Tektronix 2445 Scope and have the probe in 10X to prevent loading the circuit.

Frequencies measured at CJ3-CA2:
RX mode FSK - 8.828414 - TX mode FSK 8.830620
RX mode LSB - 8.828414 - TX mode LSB 8.828579
RX mode USB - 8.831460 - TX mode USB 8.831625
RX mode CW - 8.831460 - TX mode CW 8.830777

Frequencies measured at TP-5:
RX mode FSK - 8.828410 - TX mode FSK 8.830616
RX mode LSB - 8.828410 - TX mode LSB 8.828575
RX mode USB - 8.831450 - TX mode USB 8.831622
RX mode CW - 8.831446 - TX mode CW 8.830773

I am using a Simpson 710 Frequency counter. Specs say 1 Meg input shunted by 30 pF. The slight differences in frequency readings between CJ3-CA2 and TP-5 is probably due to the cable capacitance of the cable between IF5-13 and CJ3-CA2.

I have been taking all of these measurements with the SG switch turned off and the heater switch turned off.

Ray:

I mis-spoke in Item 2 when I said you cant measure carrier at TP-5 in Rx in any of the mode switch positions. There will be legitimate carrier but not of interest.

There will be Carrier at CA-2 and TP-5 in Rx in all positions of the mode switch that you should see, but it is meaningless for CW Tx operation. It was not correct for me to label it as "Leakage" signals.

It is there by design but not for Rx or Tx operation. CA-1 Carrier Osc signals are coupled to the CAR-2 board to amp Q3 and then on to TP-5 at IF board and then sampled and sent to the CCR lead to provide carrier oscillator signals for the Counter Mixer Board. So the carrier osc signals you were measuring at each position of the mode switch in Rx are there by design to feed the counter, but of no interest to us as not utilized for the BM and CW transmit.

So you will see approx 250mv rms at 8831.50 mhz in CW and LSB and 250mv at 8828.5mhz in LSB and FSK, but not used by the BM. BM is not used in Rx operation. So disregard these signal other than the low levels you measured cannot be correct if your counter is working

properly. I suspect you are not using O-scope properly. Are you using a 10X probe?

What I meant to say is at CA-2 and TP-5 the only frequency and level we care about is in CW and FSK positions of the mode switch in Tx. CA-2 carrier oscillator should be approx 250mv rms @ 8830.70mhz when in CW and FSK mode when flipped to send. This is what you are trying to validate. Measure at TP-5 in FSK as you know it is working. So use it to get your O-scope set up correctly and you can see approx 850mv P-P at 8830.7mhz. Once you can read that on your O-scope now switch to CW mode and flip to send to measure carrier osc signal level at TP-5.

Yes this new format gives me problems as well.

1. You are getting proper dc bias voltage to the BM. You need to confirm you are getting the Carrier Osc signal.

2. You cannot measure any Carrier freq or level at TP-5 in RX for any position of the mode switch. You may read some leakage signals in RX mode but meaningless. The BM is only used for TX and not RX. Only time you can measure any meaningful Carrier Osc frequency or level at TP-5 is in TX with the mode switch in CW or FSK. Carrier in RX mode is applied to another Mixer called the Product Detector and it arrives at IF board on IF-4 C1A terminal. You have separate Carrier Oscillators for RX and TX.

Also, the Car Level Pot has nothing to do with the Carrier Osc levels produced on the CAR Assembly Unit. The Car level pot unbalances the balanced modulator and determines the carrier output level from the BM.

You really need to measure CA-2 produced on the CAR-2 board. If you do not have 300mv of 8830.7mhz at TP-5 in CW mode when you flip to Send then you have to work your way back from TP-5 to CAR-2 board. CA2 can be checked on the 7th terminal up on the white terminal block on t

Ray:

At Position A the RF signal (from the Balanced Modulator) level reading at D7 cathode is the signal applied to the SSB filter switching diode D5. Diode D7 is not biased on in position A and no signal is passing thru your optional CW filter.

We can see that in CW mode you are biasing on the CW filter diodes D7 and D8 in Position B and Position C.

We know rig works using the SSB filter in Position A so you need to have similar output level from the CW filter in Pos C even though I do not believe those levels are accurate.

Humor me for a moment and lets say that your 800mv input is really 80mv or 28mv rms input and your 600mv output is really 60mv or 21mv rms. Now these are levels that are believable and align with the TX level diagram levels. Take a look at the levels for the TS520 and the other rigs and you will see typical levels at filter input and output.

Keeping with this same theme that you need to divide your measured O-scope levels by 10 then:

We can see that the CW filter output level in Position B and Position C is low at 44mv or 44/2.828 = 15mv rms. If you really had 15mv of 8.830.7 mhz TIF signal you should have some fairly decent RF output from the 6146 Finals. It would be close to full RF output. I dont think you have 44mv. I think you have 4.4 mv and 4.4/2.828 = 1.6mv rms output. This would mean the filter is bad.

Again easy to jump across the filter or if you have a good RF sig gen you can inject a test 8.830mhz carrier at 15 to 20 mv rms at D8 and see that you will have good RF output. .

You can prove my divide by 10 thought fairly easily if you have a standard single diode rf probe.

If you have a rf probe and VTVM or DMM you can confirm that you need to divide your measured O-scope readings by 10. A single diode germanium probe has a barrier voltage of approx 250mv. So you need a RF signal greater than that to produce a dc voltmeter reading. If you have this test gear repeat the measurements in Position A.

If you really have 800mv P-P then 800/2.282 = 283 mv rms. Your VTVM will deflect somewhat, but only read approx 283 - 250 or 33mv. Typically about lowest meter graduation on a Heath VTVM on the 1.5 vdc range is 20mv. So the meter will just barely deflect with 800mv P-P signal. If you get no meter deflection you know that you do not have the high levels you are reporting. It takes a level greater than approx 250 mv (diode barrier voltage) to get any deflection.

Lastly again take a look at the other rigs TX level diagrams in the respective Service Manuals and you will see the typical levels that do not begin to approach what your are reporting.

If you think about it the Car Level from the Carrier Osc board to TP-5 on the IF board is only 300mv rms or 850mv P-P. The Carrier output level at Buffer Amp Q18 Drain is going to be something on the order of 140mv or 400mv P-P and that is going to be coupled by a 5pf cap to D5/D7 cathodes. So it is just not possible to have 800mv P-P at D5/D7 cathodes.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

These are the readings taken with IF2 connector in all three positions (P-P values):
Position A: D7 cathode: 800mV CW, 800 mV FSK --- D8 cathode: 600mV CW, 400mV FSK
Position B: D7 cathode: 600mV CW, 800 mV FSK --- D8 cathode: 44mV CW, 400 mV FSK
Position C: D7 cathode: 260mV CW, 800 mv FSK --- D8 cathode: 40mV CW, 400 mV FSK
All readings were taken with my scope with the probe in the 10X position to prevent loading of the circuit.

These are the DC readings for D7 and D8 in all three positions (RMS values):
Position A: CW - D7 anode: -3.6V, cathode: 2.0V -- D8 anode: 0V, cathode: 9.0V
Position A: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode 8.5V
Position B: CW - D7 anode: 2.8V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.7V
Position B: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode: 8.5V
Position C: CW - D7 anode: 2.8V, cathode: 2.2V -- D8 anode: 9.3V, cathode: 8.6V
Position C: FSK - D7 anode: 2.7V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.6V

The only position I get output in CW mode is when the connector is in position A.

The CW filter is a TRIO YG-88C and I have re-soldered all connections on the filter.

I meant Cathode voltages but I think you get the idea. Measure the Anode and Cathode to ensure both diodes are being switched on. Should see approx 0.65 vdc drop across D7 and D8 as they are silicon diodes.

Not likely bad but if you need to replace I offer the following:

Should you need a diode do not use a NTE 177 sub. These are 1S1587 fast switching diodes with a fast reverse recovery time of approx 2 ns so I would not use a general purpose silicon diode as NTE sub guide suggests. Can use a NTE 519, but it has a recovery time of approx 70 ns.

I think a 1N914 or 1N4148 would be better choice at 4ns..These are still pretty commonly available.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK I forgot to give you the Anode voltages of D7 and D8 but you can just subtract approx 0.65vdc for the turn on voltage.

280mv P-P is high by my measurements, but if you read close to same in FSK-T then call it good. Certainly better than be too low.

6 mv P-P at output in CW-T is definitely a problem. As I said you can jumper the filter with a .047uf cap and see if you get CW Tx.

Is this the factory YG-88C filter?

I believe it has center frequency of 8830.7 mhz.and bandwidth of 500hz at -6dB.
I have never swept one.

It would not seem likely that you would have bad solder connections if the filter is working in FSK mode. Are you 100% certain you are not using the SSB filter in FSK mode?

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

My voltages at D7 and D8 are virtually identical to yours. I had previously measured the levels at D7 and D8. I measured 280mV P-P where C14 connects to the CW filter and only 6mV P-P out of the filter. But that was before I changed the cable to position A. I will have to move the cable back to C and re-measure tomorrow. I will also pull the IF board out and resolder the CW crystal filter connections. It may be bad solder connections as you suggest.

I just made my first contact in 17 years on 7.020 with W5TZC about 30 mins ago. He gave me a 579 which is pretty good considering my antenna is only 8 feet off the ground. I also still have to address why they final isn't tuning properly on 40 meters. It tuned max power with plate knob pointer sitting on the 5 of 3.5. It dips at 14 on 20 meters.

If I can get the CW filter issue worked out I will go through a complete tuneup of the radio following the service manual procedures.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

It is easy to test CW filter switching diodes D7 and D8. I thought you already did this and reported good?

As previously noted my plug is in C all the way toward the front panel.

Conn IF-2 pins 4 and 5 have approx 12.9vdc on them in Rx and Tx for CW-R, CW-T, FSK-R, and FSK-T.

The cathode of D7 is:
CW-R and FSK-R = 2.90vdc
CW-T and FSK- T = 2.90vdc

The cathode of D8 is : (Note: When you connect voltmeter back ground noise will drop significantly).
CW-R and FSK-R = 10.0vdc
CW-T and FSK-T = 9.80vdc

The reading will be different as the diodes are biased to different current levels. You can see the difference in the supply resistors for each diode.

I have never been able to measure TX level diagram RF voltages accurately using a 1X scope probe. It will pull your ALC indication down from FSD (40 over) to approx 25 over.

You should be able to measure the 8.830mhz TIF signal level at the input and output of the CW Xtal filter. I thought we did this a long time ago?

It is normal for the filters to have an insertion loss. Should have a minimum of approx 25mv rms at D7 input and minimum of approx 19mv rms at D8 output.

Here are my RF level measurements at D7 and D8:

Test conditons: 14.175mhz, Heater on , SG switch off, CW mode, Drive control peaked, Car Pot at 2.5 (for full scale ALC deflection or 40 over)

Boonton 92E (using 10x scope probe very close to same levels)
D7 = 58mv
D8 = 25mv

You can jumper across your CW filter with a couple of mini-grabber test leads with a 0.047uf capacitor in series.

Could have good switching diodes and good filter but bad solder connections at the filter?

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I have made a discovery that will probably tell us where the actual problem is. I was googling how to replace CW filter and found this link:
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2

So I downloaded the operators manual and looked at page 34. Kenwood is perfectly clear about this. If the plug is in position A, the CW filter is bypassed.

I put the plug in position A and can tune to full power out in CW mode. If I place the plug in position B or C I get no power out when in CW mode.

Does this indicate a bad CW filter? The filter works fine in receive mode. The only thing I have noticed is that if I switch from USB to CW the signal drops 1 S-unit when peaked for max signal in both modes.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

At this point I am using my scope with 1 meg input. If is become suspicious of the reading I switch the 10X on and take the reading that way.

An immediate problem I see is I only have 10mV P-P at the drain of Q1 in FSK mode and 0 output in CW mode. The diagram says there should be 250 mV rms there. If I pull the CW filter out of the radio, how does the CW transmit work? Does the signal then go through the USB filter or do I need to install a jumper where the CW filter was?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Yes they are RMS.

I take them at around 14.175 to 14.200 mhz with the Car Level pot advanced to the point that with the Drive Control adjusted for a peak in ALC indication at panel meter full scale deflection. Then switch to CW mode and load to approx 100 watts out and turn off SG switch. Leave Car Level and Drive control alone.

Measured values will vary depending on what test instrument you are using, length of any test jumper leads used to access the test points, line voltage.

For example 8.830mhz TIF output at the IF board and input at the RF board is shown as 0.038v. This is 38.0 mv rms rf volts or 38 x 2.828 = 107 mv P-P. So if you have approx 100mv P-P TIF you are good.

Output of the TX Mixer is 1.4v rms or 4.0v P-P. This RF drive level is now 14.175 mhz.

If you plan on doing a lot of this work suggest you invest in a RF Millivolt meter. I use a Boonton 92E. I find it loads the circuits less and just easier and faster to use.

Of coures once you get to the 1.4 volts at output of the TX Mixer the old fashioned RF probe and VTVM works great. Just have to use multi-diode probe at plate of Driver tube and control grids of the Finals. I used a Heath 309C and PK-3 probes and a IM-18 VTVM for years and still have them for fall back.

Terry,

Are the transmit levels on page 42 of the service manual correct? Are those RMS values?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Thanks Terry. I have been talking to you since you have been helping. I don't know what made me put Dave on the last message (old age maybe).

I decided to start over from the beginning and go stage by stage this afternoon. This is what I did:
(All measurements taken with Send switch operated and Mode switch in CW position. Also, the measurements are the same in both CW and FSK modes.)

I suspected D1 or L1 was bad on the CAR-II board was bad but that is not the case. I have 720mV on CA2 leaving the CAR-II board in both CW and FSK send modes. I also have 720mV P-P

on CA2 (IF5-13) on the IF board. I have 100mV P-P at the coax that connects to C92 on the IF board. On the other end of that coax where it connects to the top of T4 on the IF board I also have 100mV P-P. I would have thought the signal out of Q18 would have been stronger but maybe not.

I have 340mV at the junction of the cathode of D7 and C14 on the IF board. I have 280mV on the side of C14 where it feeds the CW filter. The signal going into the filter measures 8.830755 MHz. I only have 6mV P-P coming out of the crystal filter. Is the crystal filter used for transmit?

I connected the antenna to the radio and 20 meters is open. Tuning in CW signals in USB mode and switching to CW mode drops the signal by about 1 S-Unit when the signal is peaked for max signal in both modes.

Where do I go from here?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Are you talking Dave or Terry ? If someone is helping you off list I can back away as I have a pretty full plate right now.

I am not clear where you are measuring this 40mv P-P signal at?

Before I go I will mention that it is normal to not have a clean sine wave at TIF. It does have harmonic content and it is as you say due to LO mixing action. In this case it is coming from the VCO signal feeding back from the TX Mixer on RF board to the IF board.

This is easy to confirm with a TS-830 as you can easily unplug the VCO cable from the PLL board and the TIF signal will then be a nice clean 8.830mhz sine wave.

Dont worry about the complex waveform. Should still be able to get a reasonably close TIF measurement. It may not match exactly the levels on the TX Level Diagram,but you can compare it to the level you get with FSK carrier oscillator.

I dont use a O-scope to run TX Level diagrams once I get to the output of the TIF amp. I use a Boonton RF Millivolt meter and measure levels in rms and the "dirty" TIF signal presents no problem.

I have a new digital O-scope and it has a variety of digital filters. If I set it for a LP filter with a roll off frequency of 10mhz I can get a pretty clean 8.830 TIF sine wave display.

I dont know the Tek 2445 capability in this regard.

One final reminder is that good TIF signal level of approx 38mv rms or 107mv P-P is based on the premise that you accurately measured CA2 at the iF board of approx 300mv rms or 850mv P-P.

If that signal is not there then you would need to repeat the testing I asked you to do at the Carrier Osc board to confirm the 9vdc CW diode switching voltage is available at D1 and Q2 Buffer amp is being turned on.

I have been providing direction based on your reporting back that you have good CA-2 at Carrier board and good CA-2 at TP-5 on IF board.

If good Level at TP-5 then should have proper level at the wiper of VR-5 on the Balanced Mod. As we have discussed. No dc bias from CV and no Carrier at wiper of VR-5 then no output from the Bal Modulator.

I am pretty confident that you do have proper bias voltage from CCW to full CW on the Car Pot, but I am not certain yet that you have proper carrier output from the BM in CW mode.

Good luck.

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Dave,

I have VFO set to 14.175. With Car pot at 1200, in CW mode I get 40mV P-P in RX mode. When I flip the Send switch, the signal stays at 40 mV but it is no longer a sine wave. It is some kind of more or less sine wave with a lot of noise on it. With the Car pot at max, the noisy sinewave increases to 60 mV P-P in Send mode.

In FSK mode with Car at 1200 I get 250mV P-P in Send mode. With Car at Max I get 800 mV P-P in Send mode.

At Conn RF1-10 I get 140mV P-P in CW Send mode. I get 800mV P-P in FSK Send mode.

At the mixer output (Q1 and Q8 side of C8) I get 100 mV P-P in CW Send mode. I get 1V P-P in FSK Send mode. The signal at that point is not a sinewave but seems to have multiple signals. Probably some LO feedthrough on the mixer. The frequency counter agrees with the Kendwood readout as 14.1748 MHz.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Sorry about Q10 vs Q18. My fingers work better than what is left of my brain.

The 3 conductor plug should be positioned in forward position toward the front panel.

One thing we did not talk about is whereiyou should have the Car Level Pot set to take these measurements.

The TX Level Diagram is shown in the Service Manual. These levels were taken by Kenwood by loading the rig to approx 100 watts out at 14.175mhz and then turn the SG switch off and leave Car pot alone and Drive control alone.

Since you have no RF output in CW mode I suggest you do this for remainder of the readings:

1. VFO 14.175
2. Peak the Drive Control on receiver noise or the marker signal
3. Car Level Pot 1200
4. Heater on
5. SG switch off

6. Flip to Send to take RF drive levels

So the differences in voltages may be due to where we each have our Car Level pot set at.

Suggest you measure the voltage and frequency of the TIF signal at IF-3 Pin 2 one more time and it should be approx 250mv rms or 700mv P-P @ 8830.7mhz.

If you have close to this time to move on to the RF board. I must say this is getting a little odd as you have good output ini SSB and FSK which tells us you have good TIF level and the TX Mixer on RF Board is working which means you have good VCO (LO to the mixer).

Are you 100% certain you have no CW RF output on all bands? If so, then proceed on to the RF board with Heaters On and SG off and rig peaked as noted above.

You should have close to the values noted on the TX Level Diagram. At Conn RF-1 Pin 10 the 8.830 TIF signal level is approx 38mv rms or 108 P-P.

At output of TX Mixer should have approx 1.5v rms or 4.2v P-P rf drive at MD. At MD frequency will now be 14.175mhz transmit frequency.

If you have no RF drive or very weak at MD then need to measure the VCO level and frequency at RF-1 pin 4 and on board at TP-1. Should be close to 1.0v rms level. If no VCO try on other bands.

We are making good progress. Your Tek 2445 is perfect scope for KW Hybrid work and you apparently know how to use it and can read a schematic and can locate points on these high density boards to take measurements. This really helps.

Based on your report of no RF output in CW mode I would have thought we would have found no TIF sig at output of the IF board. TIF is not band specific and often is caused by no output from the Bal Modulator, This is why I had you start by testing for bias voltage and LO signal available. Never expected that we would be at the RF board and TX Mixer based on good RF output on other modes.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I read a little over 700mV at the drain of Q18 (actually the backside of C92 feeding the coax). I think you meant Q18 instead of Q10.

D7 and D8 are the CW switching diodes. With the mode switch in CW position, I have 2.98 volts on the anode of D7 and 2.34 volts on the cathode. I have 10.0 volts on the anode of D8 and 9.40 volts on the cathode. These voltages are there in both RX and TX, just a few 10ths of a volt lower in TX mode.

Can you confirm how the 3 pin cable ofr IF2 is supposed to plug in? It only has 3 wires but there are 5 pins on the IF board at that point. According to the chassis wiring diagram, only the first 3 pins are used as they come from S6-1.

I don't think there is anything wrong with the CW filter and the switching diodes as the CW filter works fine in RX mode.

I have 400mV P-P on Gate 1 of Q1 instead of the 160mV when flipping Send. I also have 2400mV P-P on the drain instead of 1000mV when flipping Send.

TIF signal on Conn IF-3 is 400mV P-P and the sine wave isn't quiet as clean there as it is on the drain of Q1.

Hopefully we are making progress.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Good job. Much better.

If I understand your chart you are telling me that you have approx 640mv P-P @ 8.83077 at TP-5 in CW mode with rig flipped to Send (heaters off and SG switch off). 900mv P-P is attainable by adjusting T1 on CAR-2 board, but can do later unless you want to peak it now. 640mv will work for testing.

If this is true then you have confirmed that you have the two things you need at the Balanced Mod to produce RF output from it in CW mode. 1. Offset bias voltage and 2. Proper Carrier freq and level.

From the BM output the CW signal is routed to the Crystal IF Filter and then to Q1 the Transmit IF Amp or TIF amp. TIF signal leaves the IF board and is routed to the RF board to the TX Mixer where it is mixed with VCO to produce the actual transmit rf drive signal. No TIF signal and there will be no RF drive and no RF output. Also no VCO or low VCO level and no rf drive. Lets validate that we have TIF signal in CW mode first.

Unfortunately KW didnt provide a nice test point at the output of the Balanced Mod to measure the DSBSC signal in SSB mode or the Carrier in CW mode. However, you can get on the Drain of Q10 with a hat pin or floral arrangement pin and mini-grabber test lead. If you locate the BM ring diodes D26-D29 and then output Xfmr T10 you will see Q10. It is a metal can dual gate mosfet. Looking down on the can the Drain is the upper right lead. You should read approx 800mv P-P here. This signal is routed to the Xtal filter thru switcing diodes.

Do you have the CW filter installed. It is rare but could have a bad filter. More common to have a bad switching diode.

After signal passes thru the Xtal filter it is applied to Gate 1 of TIF amp Q1. It is also a metal can dual gate mosfet and sits outside and almost between the two filters at the inboard end. Looking down on Q1 Gate 1 is at 1200. Should have approx 160mv P-P here. The Drain is at 0600 and should have approx 1000mv P-P. TIF output is on Conn IF-3 Pin 2 and should have approx 850mv P-P here. You can jump right to measuring TIF output if you want and if good then off to the RF board.

We know that you have TIF output in FSK mode as you reported good RF output in that mode. I dont kow if you keyed rig in FSK and noted the 170hz shift or not, but not important right now. Also, you should have noted that the RF output in FSK is lower as the 820 lowers the Finals Screen Grid voltage in FSK mode so the tubes plate dissipation is not exceeded in this high duty cycle mode.

That should be enough for now.

This is what I am seeing:
TP-5 and CJ3-CA2 have the same levels in CW and FSK modes: 820mV P-P in RX mode. Flipping Send switch the level drops to 640mV P-P. I have a Tektronix 2445 Scope and have the probe in 10X to prevent loading the circuit.

Frequencies measured at CJ3-CA2:
RX mode FSK - 8.828414 - TX mode FSK 8.830620
RX mode LSB - 8.828414 - TX mode LSB 8.828579
RX mode USB - 8.831460 - TX mode USB 8.831625
RX mode CW - 8.831460 - TX mode CW 8.830777

Frequencies measured at TP-5:
RX mode FSK - 8.828410 - TX mode FSK 8.830616
RX mode LSB - 8.828410 - TX mode LSB 8.828575
RX mode USB - 8.831450 - TX mode USB 8.831622
RX mode CW - 8.831446 - TX mode CW 8.830773

I am using a Simpson 710 Frequency counter. Specs say 1 Meg input shunted by 30 pF. The slight differences in frequency readings between CJ3-CA2 and TP-5 is probably due to the cable capacitance of the cable between IF5-13 and CJ3-CA2.

I have been taking all of these measurements with the SG switch turned off and the heater switch turned off.

Ray:

I mis-spoke in Item 2 when I said you cant measure carrier at TP-5 in Rx in any of the mode switch positions. There will be legitimate carrier but not of interest.

There will be Carrier at CA-2 and TP-5 in Rx in all positions of the mode switch that you should see, but it is meaningless for CW Tx operation. It was not correct for me to label it as "Leakage" signals.

It is there by design but not for Rx or Tx operation. CA-1 Carrier Osc signals are coupled to the CAR-2 board to amp Q3 and then on to TP-5 at IF board and then sampled and sent to the CCR lead to provide carrier oscillator signals for the Counter Mixer Board. So the carrier osc signals you were measuring at each position of the mode switch in Rx are there by design to feed the counter, but of no interest to us as not utilized for the BM and CW transmit.

So you will see approx 250mv rms at 8831.50 mhz in CW and LSB and 250mv at 8828.5mhz in LSB and FSK, but not used by the BM. BM is not used in Rx operation. So disregard these signal other than the low levels you measured cannot be correct if your counter is working properly. I suspect you are not using O-scope properly. Are you using a 10X probe?

What I meant to say is at CA-2 and TP-5 the only frequency and level we care about is in CW and FSK positions of the mode switch in Tx. CA-2 carrier oscillator should be approx 250mv

rms @ 8830.70mhz when in CW and FSK mode when flipped to send. This is what you are trying to validate. Measure at TP-5 in FSK as you know it is working. So use it to get your O-scope set up correctly and you can see approx 850mv P-P at 8830.7mhz. Once you can read that on your O-scope now switch to CW mode and flip to send to measure carrier osc signal level at TP-5.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Yes this new format gives me problems as well.

1. You are getting proper dc bias voltage to the BM. You need to confirm you are getting the Carrier Osc signal.

2. You cannot measure any Carrier freq or level at TP-5 in RX for any position of the mode switch. You may read some leakage signals in RX mode but meaningless. The BM is only used for TX and not RX. Only time you can measure any meaningful Carrier Osc frequency or level at TP-5 is in TX with the mode switch in CW or FSK. Carrier in RX mode is applied to another Mixer called the Product Detector and it arrives at IF board on IF-4 C1A terminal. You have separate Carrier Oscillators for RX and TX.

Also, the Car Level Pot has nothing to do with the Carrier Osc levels produced on the CAR Assembly Unit. The Car level pot unbalances the balanced modulator and determines the carrier output level from the BM.

You really need to measure CA-2 produced on the CAR-2 board. If you do not have 300mv of 8830.7mhz at TP-5 in CW mode when you flip to Send then you have to work your way back from TP-5 to CAR-2 board. CA2 can be checked on the 7th terminal up on the white terminal block on t

G'day All,

Just for information and to support the statement that the plate has two dipping spots is correct. With the pointer at the appropriate band selection the dip is small but noticeable. The second dip is not at the 180 degree mark but more like 5 o'clock position for 20m and is more noticable, the output is still the same.

Dave

Thanks. Now can you please explain to us all how a air variable capacitor that can turn physically 360 degrees and be direct drive driven can have 2 dips that are not very close to 180 degrees using the knob pointer as an indicator?

If you remove the PA cage cover what will you see?

Are the plates meshed exactly same amount at each dip only on the opposite side of the rotation ie at the normal scribed dip the plates are meshed toward the load cap and at the 2nd dip at the 1700 pointer position the plates are meshed on the final tube side?

Do we have a cap that has a different linearity curve from one side to the other?

Or is there some kind of reduction device on the pointer?

I submit (despite being told there is no reduction drive) that there is some type of reduction device on the front panel behind the knob that drives the capacitor and pointer. If you look at the knob it should have a slit in it. If it does not then make a lite mark on it or affix piece of tape on it. Now turn the knob and take the pointer thru 360 degrees of rotation and count the number of times the knob travels 360 degrees. You should find it is a ratio somewhere between 5 to 1 and 6 to 1. On the TS-830 it is 5.5 to 1 reduction. You could also mark the fiber coupler at the PA cage and count turns or take the PA cage cover off.

That makes a lot more sense than building an air variable cap with a different linearity curve on opposite sides of rotation.

So each dip is occurring at 180 degrees of rotation which is of course the same amount of plate mesh and capacitance. The pointer is just not at 180 degrees for each dip due to the drive ratio.

So Dave if you get time appreciate you putting this mystery to bed.

To the Op I submit he does have two dips and he just needs to do a complete 360 degree rotation in Tune mode to find both of them as I previously suggested. To best of my knowledge there is no padder cap used on the Tank capacitor on 20 meters that if bad could affect the normal plate dip location.

Thanks

Ray that is because you have the test cap on the Cathode sides of D7 and D8. Move the cap to the Anode sides of each and the plug to Pos C. Now you are checking the diodes as well.

This test proves that you have sufficient RF carrier level from the BM available at the Cathode of D7 to produce full output in CW.

Problem is if jumpering the filter works then which is bad? The CW filter or one or both diodes or the bias supply to the diodes?

I would focus all my efforts with the plug in Pos C to simplify reading taking.

In Pos C you need to ensure that each diode is forward biased.

D7 Cathode = 2.85vdc
D7 Anode = 2.25vdc

D8 Cathode = 9.8vdc
D8 Anode = 9.2vdc

Pretty sure you have already done this and confirmed you have diode supply voltage and good diodes so that just the filter.

Do you have an RF sig generator? If you do you can sweep the filter. It will tell you couple of things.
1. Where is Fc at (center frequency)
2. What is its attenuation

Doesnt have to be a sophisticated or accurate RF sig gen.

Can set it at around 8.0 mhz as measured by your Simpson Freq counter and set the rf output level to approx 200mv as measured by your O-scope.

Connect the output from RF sig gen to Anode of D7 and your O-scope at Anode of D8 (rig power is off) and slowly raise the frequency and see where the peak RF output voltage occurs at. Should be close to 8830.7khz. This assumes your sig gen output voltage doesnt vary greatly for small change in frequency. If it does you would need two ways to measure RF so you could ride the sig gen output to keep it constant.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

These are the readings taken with IF2 connector in all three positions (P-P values):
Position A: D7 cathode: 800mV CW, 800 mV FSK --- D8 cathode: 600mV CW, 400mV FSK
Position B: D7 cathode: 600mV CW, 800 mV FSK --- D8 cathode: 44mV CW, 400 mV FSK
Position C: D7 cathode: 260mV CW, 800 mv FSK --- D8 cathode: 40mV CW, 400 mV FSK
All readings were taken with my scope with the probe in the 10X position to prevent loading of the circuit.

These are the DC readings for D7 and D8 in all three positions (RMS values):
Position A: CW - D7 anode: -3.6V, cathode: 2.0V -- D8 anode: 0V, cathode: 9.0V
Position A: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode 8.5V
Position B: CW - D7 anode: 2.8V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.7V
Position B: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode: 8.5V
Position C: CW - D7 anode: 2.8V, cathode: 2.2V -- D8 anode: 9.3V, cathode: 8.6V
Position C: FSK - D7 anode: 2.7V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.6V

The only position I get output in CW mode is when the connector is in position A.

The CW filter is a TRIO YG-88C and I have re-soldered all connections on the filter.

I meant Cathode voltages but I think you get the idea. Measure the Anode and Cathode to ensure both diodes are being switched on. Should see approx 0.65 vdc drop across D7 and D8 as they are silicon diodes.

Not likely bad but if you need to replace I offer the following:

Should you need a diode do not use a NTE 177 sub. These are 1S1587 fast switching diodes with a fast reverse recovery time of approx 2 ns so I would not use a general purpose silicon diode as NTE sub guide suggests. Can use a NTE 519, but it has a recovery time of approx 70 ns.

I think a 1N914 or 1N4148 would be better choice at 4ns..These are still pretty commonly available.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK I forgot to give you the Anode voltages of D7 and D8 but you can just subtract approx 0.65vdc for the turn on voltage.

280mv P-P is high by my measurements, but if you read close to same in FSK-T then call it good. Certainly better than be too low.

6 mv P-P at output in CW-T is definitely a problem. As I said you can jumper the filter with a .047uf cap and see if you get CW Tx.

Is this the factory YG-88C filter?

I believe it has center frequency of 8830.7 mhz.and bandwidth of 500hz at -6dB.
I have never swept one.

It would not seem likely that you would have bad solder connections if the filter is working in FSK mode. Are you 100% certain you are not using the SSB filter in FSK mode?

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

My voltages at D7 and D8 are virtually identical to yours. I had previously measured the levels at D7 and D8. I measured 280mV P-P where C14 connects to the CW filter and only 6mV P-P out of the filter. But that was before I changed the cable to position A. I will have to move the cable back to C and re-measure tomorrow. I will also pull the IF board out and resolder the CW crystal filter connections. It may be bad solder connections as you suggest.

I just made my first contact in 17 years on 7.020 with W5TZC about 30 mins ago. He gave me a 579 which is pretty good considering my antenna is only 8 feet off the ground. I also still have to address why they final isn't tuning properly on 40 meters. It tuned max power with plate knob pointer sitting on the 5 of 3.5. It dips at 14 on 20 meters.

If I can get the CW filter issue worked out I will go through a complete tuneup of the radio following the service manual procedures.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

It is easy to test CW filter switching diodes D7 and D8. I thought you already did this and reported good?

As previously noted my plug is in C all the way toward the front panel.

Conn IF-2 pins 4 and 5 have approx 12.9vdc on them in Rx and Tx for CW-R, CW-T, FSK-R, and FSK-T.

The cathode of D7 is:
CW-R and FSK-R = 2.90vdc
CW-T and FSK- T = 2.90vdc

The cathode of D8 is : (Note: When you connect voltmeter back ground noise will drop significantly).
CW-R and FSK-R = 10.0vdc
CW-T and FSK-T = 9.80vdc

The reading will be different as the diodes are biased to different current levels. You can see the difference in the supply resistors for each diode.

I have never been able to measure TX level diagram RF voltages accurately using a 1X scope probe. It will pull your ALC indication down from FSD (40 over) to approx 25 over.

You should be able to measure the 8.830mhz TIF signal level at the input and output of the CW Xtal filter. I thought we did this a long time ago?

It is normal for the filters to have an insertion loss. Should have a minimum of approx 25mv rms at D7 input and minimum of approx 19mv rms at D8 output.

Here are my RF level measurements at D7 and D8:

Test conditons: 14.175mhz, Heater on , SG switch off, CW mode, Drive control peaked, Car Pot at 2.5 (for full scale ALC deflection or 40 over)

Boonton 92E (using 10x scope probe very close to same levels)
D7 = 58mv
D8 = 25mv

You can jumper across your CW filter with a couple of mini-grabber test leads with a 0.047uf capacitor in series.

Could have good switching diodes and good filter but bad solder connections at the filter?

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I have made a discovery that will probably tell us where the actual problem is. I was googling how to replace CW filter and found this link:
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2

So I downloaded the operators manual and looked at page 34. Kenwood is perfectly clear about this. If the plug is in position A, the CW filter is bypassed.

I put the plug in position A and can tune to full power out in CW mode. If I place the plug in position B or C I get no power out when in CW mode.

Does this indicate a bad CW filter? The filter works fine in receive mode. The only thing I have noticed is that if I switch from USB to CW the signal drops 1 S-unit when peaked for max signal in both modes.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

At this point I am using my scope with 1 meg input. If is become suspicious of the reading I switch the 10X on and take the reading that way.

An immediate problem I see is I only have 10mV P-P at the drain of Q1 in FSK mode and 0 output in CW mode. The diagram says there should be 250 mV rms there. If I pull the CW filter out of the radio, how does the CW transmit work? Does the signal then go through the USB filter or do I need to install a jumper where the CW filter was?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Yes they are RMS.

I take them at around 14.175 to 14.200 mhz with the Car Level pot advanced to the point that with the Drive Control adjusted for a peak in ALC indication at panel meter full scale deflection. Then switch to CW mode and load to approx 100 watts out and turn off SG switch. Leave Car Level and Drive control alone.

Measured values will vary depending on what test instrument you are using, length of any test jumper leads used to access the test points, line voltage.

For example 8.830mhz TIF output at the IF board and input at the RF board is shown as 0.038v. This is 38.0 mv rms rf volts or 38 x 2.828 = 107 mv P-P. So if you have approx 100mv P-P TIF you are good.

Output of the TX Mixer is 1.4v rms or 4.0v P-P. This RF drive level is now 14.175 mhz.

If you plan on doing a lot of this work suggest you invest in a RF Millivolt meter. I use a Boonton 92E. I find it loads the circuits less and just easier and faster to use.

Of coures once you get to the 1.4 volts at output of the TX Mixer the old fashioned RF probe and VTVM works great. Just have to use multi-diode probe at plate of Driver tube and control grids of the Finals. I used a Heath 309C and PK-3 probes and a IM-18 VTVM for years and still have them for fall back.

Terry,

Are the transmit levels on page 42 of the service manual correct? Are those RMS values?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Thanks Terry. I have been talking to you since you have been helping. I don't know what made me put Dave on the last message (old age maybe).

I decided to start over from the beginning and go stage by stage this afternoon. This is what I did:
(All measurements taken with Send switch operated and Mode switch in CW position. Also, the measurements are the same in both CW and FSK modes.)

I suspected D1 or L1 was bad on the CAR-II board was bad but that is not the case. I have 720mV on CA2 leaving the CAR-II board in both CW and FSK send modes. I also have 720mV P-P on CA2 (IF5-13) on the IF board. I have 100mV P-P at the coax that connects to C92 on the IF board. On the other end of that coax where it connects to the top of T4 on the IF board I also have 100mV P-P. I would have thought the signal out of Q18 would have been stronger but maybe not.

I have 340mV at the junction of the cathode of D7 and C14 on the IF board. I have 280mV on the side of C14 where it feeds the CW filter. The signal going into the filter measures

8.830755 MHz. I only have 6mV P-P coming out of the crystal filter. Is the crystal filter used for transmit?

I connected the antenna to the radio and 20 meters is open. Tuning in CW signals in USB mode and switching to CW mode drops the signal by about 1 S-Unit when the signal is peaked for max signal in both modes.

Where do I go from here?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Are you talking Dave or Terry ? If someone is helping you off list I can back away as I have a pretty full plate right now.

I am not clear where you are measuring this 40mv P-P signal at?

Before I go I will mention that it is normal to not have a clean sine wave at TIF. It does have harmonic content and it is as you say due to LO mixing action. In this case it is coming from the VCO signal feeding back from the TX Mixer on RF board to the IF board.

This is easy to confirm with a TS-830 as you can easily unplug the VCO cable from the PLL board and the TIF signal will then be a nice clean 8.830mhz sine wave.

Dont worry about the complex waveform. Should still be able to get a reasonably close TIF measurement. It may not match exactly the levels on the TX Level Diagram,but you can compare it to the level you get with FSK carrier oscillator.

I dont use a O-scope to run TX Level diagrams once I get to the output of the TIF amp. I use a Boonton RF Millivolt meter and measure levels in rms and the "dirty" TIF signal presents no problem.

I have a new digital O-scope and it has a variety of digital filters. If I set it for a LP filter with a roll off frequency of 10mhz I can get a pretty clean 8.830 TIF sine wave display.

I dont know the Tek 2445 capability in this regard.

One final reminder is that good TIF signal level of approx 38mv rms or 107mv P-P is based on the premise that you accurately measured CA2 at the iF board of approx 300mv rms or 850mv P-P.

If that signal is not there then you would need to repeat the testing I asked you to do at the Carrier Osc board to confirm the 9vdc CW diode switching voltage is available at D1 and Q2 Buffer amp is being turned on.

I have been providing direction based on your reporting back that you have good CA-2 at Carrier board and good CA-2 at TP-5 on IF board.

If good Level at TP-5 then should have proper level at the wiper of VR-5 on the Balanced Mod. As we have discussed. No dc bias from CV and no Carrier at wiper of VR-5 then no output from the Bal Modulator.

I am pretty confident that you do have proper bias voltage from CCW to full CW on the Car Pot, but I am not certain yet that you have proper carrier output from the BM in CW mode.

Good luck.

Terry K9TW.

Dave,

I have VFO set to 14.175. With Car pot at 1200, in CW mode I get 40mV P-P in RX mode. When I flip the Send switch, the signal stays at 40 mV but it is no longer a sine wave. It is some kind of more or less sine wave with a lot of noise on it. With the Car pot at max, the noisy sinewave increases to 60 mV P-P in Send mode.

In FSK mode with Car at 1200 I get 250mV P-P in Send mode. With Car at Max I get 800 mV P-P in Send mode.

At Conn RF1-10 I get 140mV P-P in CW Send mode. I get 800mV P-P in FSK Send mode.

At the mixer output (Q1 and Q8 side of C8) I get 100 mV P-P in CW Send mode. I get 1V P-P in FSK Send mode. The signal at that point is not a sinewave but seems to have multiple signals. Probably some LO feedthrough on the mixer. The frequency counter agrees with the Kendwood readout as 14.1748 MHz.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Sorry about Q10 vs Q18. My fingers work better than what is left of my brain.

The 3 conductor plug should be positioned in forward position toward the front panel.

One thing we did not talk about is whereiyou should have the Car Level Pot set to take these measurements.

The TX Level Diagram is shown in the Service Manual. These levels were taken by Kenwood by loading the rig to approx 100 watts out at 14.175mhz and then turn the SG switch off and leave Car pot alone and Drive control alone.

Since you have no RF output in CW mode I suggest you do this for remainder of the readings:

1. VFO 14.175
2. Peak the Drive Control on receiver noise or the marker signal
3. Car Level Pot 1200
4. Heater on
5. SG switch off
6. Flip to Send to take RF drive levels

So the differences in voltages may be due to where we each have our Car Level pot set at.

Suggest you measure the voltage and frequency of the TIF signal at IF-3 Pin 2 one more time and it should be approx 250mv rms or 700mv P-P @ 8830.7mhz.

If you have close to this time to move on to the RF board. I must say this is getting a little odd as you have good output ini SSB and FSK which tells us you have good TIF level and the TX Mixer on RF Board is working which means you have good VCO (LO to the mixer).

Are you 100% certain you have no CW RF output on all bands? If so, then proceed on to the RF board with Heaters On and SG off and rig peaked as noted above.

You should have close to the values noted on the TX Level Diagram. At Conn RF-1 Pin 10 the 8.830 TIF signal level is approx 38mv rms or 108 P-P.

At output of TX Mixer should have approx 1.5v rms or 4.2v P-P rf drive at MD. At MD frequency will now be 14.175mhz transmit frequency.

If you have no RF drive or very weak at MD then need to measure the VCO level and frequency at RF-1 pin 4 and on board at TP-1. Should be close to 1.0v rms level. If no VCO try on other bands.

We are making good progress. Your Tek 2445 is perfect scope for KW Hybrid work and you apparently know how to use it and can read a schematic and can locate points on these high density boards to take measurements. This really helps.

Based on your report of no RF output in CW mode I would have thought we would have found no TIF sig at output of the IF board. TIF is not band specific and often is caused by no output from the Bal Modulator, This is why I had you start by testing for bias voltage and LO signal available. Never expected that we would be at the RF board and TX Mixer based on good RF output on other modes.

Terry,

I read a little over 700mV at the drain of Q18 (actually the backside of C92 feeding the coax). I think you meant Q18 instead of Q10.

D7 and D8 are the CW switching diodes. With the mode switch in CW position, I have 2.98 volts on the anode of D7 and 2.34 volts on the cathode. I have 10.0 volts on the anode of D8 and 9.40 volts on the cathode. These voltages are there in both RX and TX, just a few 10ths of a volt lower in TX mode.

Can you confirm how the 3 pin cable ofr IF2 is supposed to plug in? It only has 3 wires but there are 5 pins on the IF board at that point. According to the chassis wiring diagram, only the first 3 pins are used as they come from S6-1.

I don't think there is anything wrong with the CW filter and the switching diodes as the CW filter works fine in RX mode.

I have 400mV P-P on Gate 1 of Q1 instead of the 160mV when flipping Send. I also have 2400mV P-P on the drain instead of 1000mV when flipping Send.

TIF signal on Conn IF-3 is 400mV P-P and the sine wave isn't quiet as clean there as it is on the drain of Q1.

Hopefully we are making progress.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Good job. Much better.

If I understand your chart you are telling me that you have approx 640mv P-P @ 8.83077 at TP-5 in CW mode with rig flipped to Send (heaters off and SG switch off). 900mv P-P is attainable by adjusting T1 on CAR-2 board, but can do later unless you want to peak it now. 640mv will work for testing.

If this is true then you have confirmed that you have the two things you need at the Balanced Mod to produce RF output from it in CW mode. 1. Offset bias voltage and 2. Proper Carrier freq and level.

From the BM output the CW signal is routed to the Crystal IF Filter and then to Q1 the Transmit IF Amp or TIF amp. TIF signal leaves the IF board and is routed to the RF board to the TX Mixer where it is mixed with VCO to produce the actual transmit rf drive signal. No TIF signal and there will be no RF drive and no RF output. Also no VCO or low VCO level and no rf drive. Lets validate that we have TIF signal in CW mode first.

Unfortunately KW didnt provide a nice test point at the output of the Balanced Mod to measure the DSBSC signal in SSB mode or the Carrier in CW mode. However, you can get on the Drain of Q10 with a hat pin or floral arrangement pin and mini-grabber test lead. If you locate the BM ring diodes D26-D29 and then output Xfmr T10 you will see Q10. It is a metal can dual gate mosfet. Looking down on the can the Drain is the upper right lead. You should read approx 800mv P-P here. This signal is routed to the Xtal filter thru switcing diodes.

Do you have the CW filter installed. It is rare but could have a bad filter. More common to have a bad switching diode.

After signal passes thru the Xtal filter it is applied to Gate 1 of TIF amp Q1. It is also a metal can dual gate mosfet and sits outside and almost between the two filters at the inboard end. Looking down on Q1 Gate 1 is at 1200. Should have approx 160mv P-P here. The Drain is at 0600 and should have approx 1000mv P-P. TIF output is on Conn IF-3 Pin 2 and should have approx 850mv P-P here. You can jump right to measuring TIF output if you want and if good then off to the RF board.

We know that you have TIF output in FSK mode as you reported good RF output in that mode. I dont kow if you keyed rig in FSK and noted the 170hz shift or not, but not important right now. Also, you should have noted that the RF output in FSK is lower as the 820 lowers the Finals Screen Grid voltage in FSK mode so the tubes plate dissipation is not exceeded in this high duty cycle mode.

That should be enough for now.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

This is what I am seeing:
TP-5 and CJ3-CA2 have the same levels in CW and FSK modes: 820mV P-P in RX mode. Flipping Send switch the level drops to 640mV P-P. I have a Tektronix 2445 Scope and have the probe

in 10X to prevent loading the circuit.

Frequencies measured at CJ3-CA2:
RX mode FSK - 8.828414 - TX mode FSK 8.830620
RX mode LSB - 8.828414 - TX mode LSB 8.828579
RX mode USB - 8.831460 - TX mode USB 8.831625
RX mode CW - 8.831460 - TX mode CW 8.830777

Frequencies measured at TP-5:
RX mode FSK - 8.828410 - TX mode FSK 8.830616
RX mode LSB - 8.828410 - TX mode LSB 8.828575
RX mode USB - 8.831450 - TX mode USB 8.831622
RX mode CW - 8.831446 - TX mode CW 8.830773

I am using a Simpson 710 Frequency counter. Specs say 1 Meg input shunted by 30 pF. The slight differences in frequency readings between CJ3-CA2 and TP-5 is probably due to the cable capacitance of the cable between IF5-13 and CJ3-CA2.

I have been taking all of these measurements with the SG switch turned off and the heater switch turned off.

Ray:

I mis-spoke in Item 2 when I said you cant measure carrier at TP-5 in Rx in any of the mode switch positions. There will be legitimate carrier but not of interest.

There will be Carrier at CA-2 and TP-5 in Rx in all positions of the mode switch that you should see, but it is meaningless for CW Tx operation. It was not correct for me to label it as "Leakage" signals.

It is there by design but not for Rx or Tx operation. CA-1 Carrier Osc signals are coupled to the CAR-2 board to amp Q3 and then on to TP-5 at IF board and then sampled and sent to the CCR lead to provide carrier oscillator signals for the Counter Mixer Board. So the carrier osc signals you were measuring at each position of the mode switch in Rx are there by design to feed the counter, but of no interest to us as not utilized for the BM and CW transmit.

So you will see approx 250mv rms at 8831.50 mhz in CW and LSB and 250mv at 8828.5mhz in LSB and FSK, but not used by the BM. BM is not used in Rx operation. So disregard these signal other than the low levels you measured cannot be correct if your counter is working properly. I suspect you are not using O-scope properly. Are you using a 10X probe?

What I meant to say is at CA-2 and TP-5 the only frequency and level we care about is in CW and FSK positions of the mode switch in Tx. CA-2 carrier oscillator should be approx 250mv rms @ 8830.70mhz when in CW and FSK mode when flipped to send. This is what you are trying to validate. Measure at TP-5 in FSK as you know it is working. So use it to get your O-scope set up correctly and you can see approx 850mv P-P at 8830.7mhz. Once you can read that on your O-scope now switch to CW mode and flip to send to measure carrier osc signal level at TP-5.

Yes this new format gives me problems as well.

1. You are getting proper dc bias voltage to the BM. You need to confirm you are getting the Carrier Osc signal.

2. You cannot measure any Carrier freq or level at TP-5 in RX for any position of the mode switch. You may read some leakage signals in RX mode but meaningless. The BM is only used for TX and not RX. Only time you can measure any meaningful Carrier Osc frequency or level at TP-5 is in TX with the mode switch in CW or FSK. Carrier in RX mode is applied to another Mixer called the Product Detector and it arrives at IF bo

Terry,

Just for interest, you said "So each dip is occurring at 180 degrees of rotation which is of course the same amount of plate mesh and capacitance."

Take an example of the cap starting at 0% mesh.
If the dip is found at 10 % mesh cw, the dip will also be found at 10 % mesh ccw with a small angle between them, not 180%.
This leads to two possible cases of one dip per rotation of the cap if:

1) the dip occurs at 100% meshed
or
2) the dip occurs at 0% meshed

What's the probability of case 1 or 2?

Cheers

Good day!
I had to read this twice before I realised that what we had here was exactly my G5RV.
Except! Why do people continue to try and feed it with coax and no ATU.
You can get some rather poor SWR that way and I have even heard of coax melting under higher powers.
If you want to use a G5RV then try a Z match. This will give you 1:1 SWR on almost all bands.
Mine was not too great on 10 MHz but then I tried the expedient of putting a 1uH (self supporting) heavy wire inductor into one side of the ladder line and all was fine.
As wire antennas go it takes a bit of beating. But you have to be able to get your reactances
right for any particular frequency.
BTW I worked Ecuador from NZ recently using a 2 tube 1934 QST receiver and my TS820's TX.

Dave:

You are correct if you started with the plates 100 % open and dip occurred at 10% meshed CW then it would also occur at 10% meshed in the CCW direction and that would be significantly less than 180 degrees. Similarly if you continued to rotate shaft CW back to 10% mesh that would be much more than 180 degrees

Same with 3.5 mhz where plates are 100 % meshed at full CCW as indicated on the painted white arc semi circle travel. So to get back to 100% mesh you would have to turn the cap 360 degrees either direction to get back to max capacitance.

It depends on what band you are on as to how many degrees between the two dips.

I mispoke about the 180 degrees.

Point I am trying to make is the knob pointer will not be 180 degrees from the normal white painted arc dip location when you rotate the shaft and locate the 2nd dip. However at that point you will be at the same electrical point and have the same amount of capacitor plate mesh and the same capacitance to resonate with the particular tank coil tap you have selected with the band switch.

What got me into this discussion was the direction that was given to the Op to rotate the cap 180 degrees or rotate from North to South and he should see the other dip and that is not correct.

I was worried the Op would just turn the Tank cap 180 degrees and key rig in Tune and move knob a few degrees back and forth and find no dip and report back that he only has 1 dip.

> try and get these cores but I will keep trying.

By any chance does anyone on this list have precise measurements of size - length, diameter, thread pitch (in either SAE or Metric measurements, I will convert as needed), as well as ferric composition data for these hard-to-find slugs?

I am NOT stupid enough to be thinking about wanting anyone to pull one out of a working rig! Instead, if someone is -already- having trouble in that area, and has one in hand, taking some precise measurements wouldn't be much of an additional chore.

With that information it might (MIGHT! NO BETS, NOT ANY SORT OF GUARANTEE.) be possible to find some manufacturer making a similar-enough slug for some other coil in some other kind of equipment that will allow us to scavenge some spares. I would be willing to look into it, I seem to recall hearing about a Polish company which might be still making such things.

So, if anyone has one of the slugs to hand, and the bit of skill required to read a caliper or micrometer, that would be a great start.

The type of ferrite is another item, it might be possible to get that information from Kenwood if it isn't already known. (The size and density of the granules, as well as the specific composition of the ferrite compound, makes a difference in the permeability of the core. It may be possible to compensate for it, at least to some extent, if we can't find an exact match.)

If we cannot find one to scavenge, between the lot of us and all the people and companies with which we together have contact, there ought to be some way to maneuver all that into at least one minimal production run of tuning slugs; a small enough run that we (as a group) could afford paying for it, but large enough to keep all of our rigs in coil tuning slugs for the foreseeable future.

It would probably require everyone who wants some to chip in a small amount to buy the entire output of a run (however many that might be), but you would be guaranteed enough slugs for all the hybrid rigs you could ever want. Those who didn't chip in initially would have to pay a premium price later (likely from one of those who did use foresight, and therefore have excess parts to their requirements).

Prices and such would be figured IF we can find someone who has or can make what we need.

I don't know about anyone else, but I think this might be worth looking into, at the very least. I have done similar things when we needed parts for R-390A receivers when I was still in the USAF. (A small West German machine shop made us a batch of one specific gear for the tuner drive transmission monstrosity, one which kept breaking on us and quickly went out of stock in the spares down in the electronic repair shop. That alone tells you it was awhile ago, right there, more than the fact that we were still using the R-390A; there was still an East and a West Germany then. But you might be amazed to find out that the last government order for Collins R-390A receivers was

1984!)

There is a site for help in repairing old (mostly military) 'valved' HF rigs:

http://www.vk2bv.org/radio/parry3.htm .

I find it fascinating, as well as quite helpful sometimes.

So, measurements of that tuning slug, anyone??

Terry,

With the .047 cap on the anodes of D7 and D8 I am able to obtain full output in CW mode. Also, both diodes are forward biased in CW Send mode as I see approximately .6 volts drop across them in Pos C. The voltages are about .1 volt lower than what you are showing.

Do you know the impedance of the crystal filters in the TS-820? This is the signal source I have to use to test with:
http://www.oocities.org/hagtronics/source/index.html
http://www.oocities.org/hagtronics/source/index.html
It has a 50 ohm output. I also have a HP 3314A I could use but it is also 50 ohms out.

With the signal source set to -1 dB out and in and out connections at the anodes of D7 and D8, I get these are the readings I get:

8.8300 - -46.9 dB
8.8301 - -33.3 dB
8.8302 - -19.5 dB
8.8303 - -14.4 dB
8.8304 - -17.5 dB
8.8305 - -26.4 dB
8.8306 - -28-5 dB
8.8307 - -42.5 dB
8.8308 - -49.5 dB
8.8309 - -49.7 dB
8.8310 - -50.0 dB

The filter FC appears to be at 8.8303. My scope with 1 meg load agrees with this as I see the peak on it at the same frequency. I don't know how much the 50 ohm generator and power meter loads are affecting the filter.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray that is because you have the test cap on the Cathode sides of D7 and D8. Move the cap to the Anode sides of each and the plug to Pos C. Now you are checking the diodes as well.

This test proves that you have sufficient RF carrier level from the BM available at the Cathode of D7 to produce full output in CW.

Problem is if jumpering the filter works then which is bad? The CW filter or one or both diodes or the bias supply to the diodes?

I would focus all my efforts with the plug in Pos C to simplify reading taking.

In Pos C you need to ensure that each diode is forward biased.

D7 Cathode = 2.85vdc
D7 Anode = 2.25vdc

D8 Cathode = 9.8vdc
D8 Anode = 9.2vdc

Pretty sure you have already done this and confirmed you have diode supply voltage and good diodes so that just the filter.

Do you have an RF sig generator? If you do you can sweep the filter. It will tell you couple of things.
1. Where is Fc at (center frequency)
2. What is its attenuation

Doesnt have to be a sophisticated or accurate RF sig gen.

Can set it at around 8.0 mhz as measured by your Simpson Freq counter and set the rf output level to approx 200mv as measured by your O-scope.

Connect the output from RF sig gen to Anode of D7 and your O-scope at Anode of D8 (rig power is off) and slowly raise the frequency and see where the peak RF output voltage occurs at. Should be close to 8830.7khz. This assumes your sig gen output voltage doesnt vary greatly for small change in frequency. If it does you would need two ways to measure RF so you could ride the sig gen output to keep it constant.

Terry, with a .047 capacitor across the CW filter, I get full output in CW mode regardless of what position the IF2 connector is in.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

These are the readings taken with IF2 connector in all three positions (P-P values):
Position A: D7 cathode: 800mV CW, 800 mV FSK --- D8 cathode: 600mV CW, 400mV FSK
Position B: D7 cathode: 600mV CW, 800 mV FSK --- D8 cathode: 44mV CW, 400 mV FSK
Position C: D7 cathode: 260mV CW, 800 mv FSK --- D8 cathode: 40mV CW, 400 mV FSK
All readings were taken with my scope with the probe in the 10X position to prevent loading of the circuit.

These are the DC readings for D7 and D8 in all three positions (RMS values):
Position A: CW - D7 anode: -3.6V, cathode: 2.0V -- D8 anode: 0V, cathode: 9.0V
Position A: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode 8.5V
Position B: CW - D7 anode: 2.8V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.7V
Position B: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode: 8.5V
Position C: CW - D7 anode: 2.8V, cathode: 2.2V -- D8 anode: 9.3V, cathode: 8.6V
Position C: FSK - D7 anode: 2.7V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.6V

The only position I get output in CW mode is when the connector is in position A.

The CW filter is a TRIO YG-88C and I have re-soldered all connections on the filter.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

I meant Cathode voltages but I think you get the idea. Measure the Anode and Cathode to ensure both diodes are being switched on. Should see approx 0.65 vdc drop across D7 and D8 as they are silicon diodes.

Not likely bad but if you need to replace I offer the following:

Should you need a diode do not use a NTE 177 sub. These are 1S1587 fast switching diodes with a fast reverse recovery time of approx 2 ns so I would not use a general purpose silicon diode as NTE sub guide suggests. Can use a NTE 519, but it has a recovery time of approx 70 ns.

I think a 1N914 or 1N4148 would be better choice at 4ns..These are still pretty commonly available.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK I forgot to give you the Anode voltages of D7 and D8 but you can just subtract approx 0.65vdc for the turn on voltage.

280mv P-P is high by my measurements, but if you read close to same in FSK-T then call it good. Certainly better than be too low.

6 mv P-P at output in CW-T is definitely a problem. As I said you can jumper the filter with a .047uf cap and see if you get CW Tx.

Is this the factory YG-88C filter?

I believe it has center frequency of 8830.7 mhz.and bandwidth of 500hz at -6dB.
I have never swept one.

It would not seem likely that you would have bad solder connections if the filter is working in FSK mode. Are you 100% certain you are not using the SSB filter in FSK mode?

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

My voltages at D7 and D8 are virtually identical to yours. I had previously measured the levels at D7 and D8. I measured 280mV P-P where C14 connects to the CW filter and only 6mV P-P out of the filter. But that was before I changed the cable to position A. I will have to move the cable back to C and re-measure tomorrow. I will also pull the IF board out and resolder the CW crystal filter connections. It may be bad solder connections as you suggest.

I just made my first contact in 17 years on 7.020 with W5TZC about 30 mins ago. He gave me a 579 which is pretty good considering my antenna is only 8 feet off the ground. I also

still have to address why they final isn't tuning properly on 40 meters. It tuned max power with plate knob pointer sitting on the 5 of 3.5. It dips at 14 on 20 meters.

If I can get the CW filter issue worked out I will go through a complete tuneup of the radio following the service manual procedures.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

It is easy to test CW filter switching diodes D7 and D8. I thought you already did this and reported good?

As previously noted my plug is in C all the way toward the front panel.

Conn IF-2 pins 4 and 5 have approx 12.9vdc on them in Rx and Tx for CW-R, CW-T, FSK-R, and FSK-T.

The cathode of D7 is:
CW-R and FSK-R = 2.90vdc
CW-T and FSK- T = 2.90vdc

The cathode of D8 is : (Note: When you connect voltmeter back ground noise will drop significantly).
CW-R and FSK-R = 10.0vdc
CW-T and FSK-T = 9.80vdc

The reading will be different as the diodes are biased to different current levels. You can see the difference in the supply resistors for each diode.

I have never been able to measure TX level diagram RF voltages accurately using a 1X scope probe. It will pull your ALC indication down from FSD (40 over) to approx 25 over.

You should be able to measure the 8.830mhz TIF signal level at the input and output of the CW Xtal filter. I thought we did this a long time ago?

It is normal for the filters to have an insertion loss. Should have a minimum of approx 25mv rms at D7 input and minimum of approx 19mv rms at D8 output.

Here are my RF level measurements at D7 and D8:

Test conditons: 14.175mhz, Heater on , SG switch off, CW mode, Drive control peaked, Car Pot at 2.5 (for full scale ALC deflection or 40 over)

Boonton 92E (using 10x scope probe very close to same levels)
D7 = 58mv
D8 = 25mv

You can jumper across your CW filter with a couple of mini-grabber test leads with a 0.047uf capacitor in series.

Could have good switching diodes and good filter but bad solder connections at the filter?

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I have made a discovery that will probably tell us where the actual problem is. I was googling how to replace CW filter and found this link:
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2

So I downloaded the operators manual and looked at page 34. Kenwood is perfectly clear about this. If the plug is in position A, the CW filter is bypassed.

I put the plug in position A and can tune to full power out in CW mode. If I place the plug in position B or C I get no power out when in CW mode.

Does this indicate a bad CW filter? The filter works fine in receive mode. The only thing I have noticed is that if I switch from USB to CW the signal drops 1 S-unit when peaked for max signal in both modes.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

At this point I am using my scope with 1 meg input. If is become suspicious of the reading I switch the 10X on and take the reading that way.

An immediate problem I see is I only have 10mV P-P at the drain of Q1 in FSK mode and 0 output in CW mode. The diagram says there should be 250 mV rms there. If I pull the CW filter out of the radio, how does the CW transmit work? Does the signal then go through the USB filter or do I need to install a jumper where the CW filter was?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Yes they are RMS.

I take them at around 14.175 to 14.200 mhz with the Car Level pot advanced to the point that with the Drive Control adjusted for a peak in ALC indication at panel meter full scale deflection. Then switch to CW mode and load to approx 100 watts out and turn off SG switch. Leave Car Level and Drive control alone.

Measured values will vary depending on what test instrument you are using, length of any test jumper leads used to access the test points, line voltage.

For example 8.830mhz TIF output at the IF board and input at the RF board is shown as 0.038v. This is 38.0 mv rms rf volts or 38 x 2.828 = 107 mv P-P. So if you have approx 100mv P-P TIF you are good.

Output of the TX Mixer is 1.4v rms or 4.0v P-P. This RF drive level is now 14.175 mhz.

If you plan on doing a lot of this work suggest you invest in a RF Millivolt meter. I use a Boonton 92E. I find it loads the circuits less and just easier and faster to use.

Of coures once you get to the 1.4 volts at output of the TX Mixer the old fashioned RF probe and VTVM works great. Just have to use multi-diode probe at plate of Driver tube and control grids of the Finals. I used a Heath 309C and PK-3 probes and a IM-18 VTVM for years and still have them for fall back.

Are the transmit levels on page 42 of the service manual correct? Are those RMS values?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Thanks Terry. I have been talking to you since you have been helping. I don't know what made me put Dave on the last message (old age maybe).

I decided to start over from the beginning and go stage by stage this afternoon. This is what I did:
(All measurements taken with Send switch operated and Mode switch in CW position. Also, the measurements are the same in both CW and FSK modes.)

I suspected D1 or L1 was bad on the CAR-II board was bad but that is not the case. I have 720mV on CA2 leaving the CAR-II board in both CW and FSK send modes. I also have 720mV P-P on CA2 (IF5-13) on the IF board. I have 100mV P-P at the coax that connects to C92 on the IF board. On the other end of that coax where it connects to the top of T4 on the IF board I also have 100mV P-P. I would have thought the signal out of Q18 would have been stronger but maybe not.

I have 340mV at the junction of the cathode of D7 and C14 on the IF board. I have 280mV on the side of C14 where it feeds the CW filter. The signal going into the filter measures 8.830755 MHz. I only have 6mV P-P coming out of the crystal filter. Is the crystal filter used for transmit?

I connected the antenna to the radio and 20 meters is open. Tuning in CW signals in USB mode and switching to CW mode drops the signal by about 1 S-Unit when the signal is peaked for max signal in both modes.

Where do I go from here?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Are you talking Dave or Terry ? If someone is helping you off list I can back away as I have a pretty full plate right now.

I am not clear where you are measuring this 40mv P-P signal at?

Before I go I will mention that it is normal to not have a clean sine wave at TIF. It does have harmonic content and it is as you say due to LO mixing action. In this case it is coming from the VCO signal feeding back from the TX Mixer on RF board to the IF board.

This is easy to confirm with a TS-830 as you can easily unplug the VCO cable from the PLL board and the TIF signal will then be a nice clean 8.830mhz sine wave.

Dont worry about the complex waveform. Should still be able to get a reasonably close TIF measurement. It may not match exactly the levels on the TX Level Diagram,but you can compare it to the level you get with FSK carrier oscillator.

I dont use a O-scope to run TX Level diagrams once I get to the output of the TIF amp. I use a Boonton RF Millivolt meter and measure levels in rms and the "dirty" TIF signal presents no problem.

I have a new digital O-scope and it has a variety of digital filters. If I set it for a LP filter with a roll off frequency of 10mhz I can get a pretty clean 8.830 TIF sine wave display.

I dont know the Tek 2445 capability in this regard.

One final reminder is that good TIF signal level of approx 38mv rms or 107mv P-P is based on the premise that you accurately measured CA2 at the iF board of approx 300mv rms or 850mv P-P.

If that signal is not there then you would need to repeat the testing I asked you to do at the Carrier Osc board to confirm the 9vdc CW diode switching voltage is available at D1 and Q2 Buffer amp is being turned on.

I have been providing direction based on your reporting back that you have good CA-2 at Carrier board and good CA-2 at TP-5 on IF board.

If good Level at TP-5 then should have proper level at the wiper of VR-5 on the Balanced Mod. As we have discussed. No dc bias from CV and no Carrier at wiper of VR-5 then no output from the Bal Modulator.

I am pretty confident that you do have proper bias voltage from CCW to full CW on the Car Pot, but I am not certain yet that you have proper carrier output from the BM in CW mode.

Good luck.

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Dave,

I have VFO set to 14.175. With Car pot at 1200, in CW mode I get 40mV P-P in RX mode. When I flip the Send switch, the signal stays at 40 mV but it is no longer a sine wave. It is some kind of more or less sine wave with a lot of noise on it. With the Car pot at max, the noisy sinewave increases to 60 mV P-P in Send mode.

In FSK mode with Car at 1200 I get 250mV P-P in Send mode. With Car at Max I get 800 mV P-P in Send mode.

At Conn RF1-10 I get 140mV P-P in CW Send mode. I get 800mV P-P in FSK Send mode.

At the mixer output (Q1 and Q8 side of C8) I get 100 mV P-P in CW Send mode. I get 1V P-P in FSK Send mode. The signal at that point is not a sinewave but seems to have multiple

signals. Probably some LO feedthrough on the mixer. The frequency counter agrees with the Kendwood readout as 14.1748 MHz.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Sorry about Q10 vs Q18. My fingers work better than what is left of my brain.

The 3 conductor plug should be positioned in forward position toward the front panel.

One thing we did not talk about is whereiyou should have the Car Level Pot set to take these measurements.

The TX Level Diagram is shown in the Service Manual. These levels were taken by Kenwood by loading the rig to approx 100 watts out at 14.175mhz and then turn the SG switch off and leave Car pot alone and Drive control alone.

Since you have no RF output in CW mode I suggest you do this for remainder of the readings:

1. VFO 14.175
2. Peak the Drive Control on receiver noise or the marker signal
3. Car Level Pot 1200
4. Heater on
5. SG switch off
6. Flip to Send to take RF drive levels

So the differences in voltages may be due to where we each have our Car Level pot set at.

Suggest you measure the voltage and frequency of the TIF signal at IF-3 Pin 2 one more time and it should be approx 250mv rms or 700mv P-P @ 8830.7mhz.

If you have close to this time to move on to the RF board. I must say this is getting a little odd as you have good output ini SSB and FSK which tells us you have good TIF level and the TX Mixer on RF Board is working which means you have good VCO (LO to the mixer).

Are you 100% certain you have no CW RF output on all bands? If so, then proceed on to the RF board with Heaters On and SG off and rig peaked as noted above.

You should have close to the values noted on the TX Level Diagram. At Conn RF-1 Pin 10 the 8.830 TIF signal level is approx 38mv rms or 108 P-P.

At output of TX Mixer should have approx 1.5v rms or 4.2v P-P rf drive at MD. At MD frequency will now be 14.175mhz transmit frequency.

If you have no RF drive or very weak at MD then need to measure the VCO level and frequency at RF-1 pin 4 and on board at TP-1. Should be close to 1.0v rms level. If no VCO try on other bands.

We are making good progress. Your Tek 2445 is perfect scope for KW Hybrid work and you apparently know how to use it and can read a schematic and can locate points on these high density boards to take measurements. This really helps.

Based on your report of no RF output in CW mode I would have thought we would have found no TIF sig at output of the IF board. TIF is not band specific and often is caused by no

output from the Bal Modulator, This is why I had you start by testing for bias voltage and LO signal available. Never expected that we would be at the RF board and TX Mixer based on good RF output on other modes.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I read a little over 700mV at the drain of Q18 (actually the backside of C92 feeding the coax). I think you meant Q18 instead of Q10.

D7 and D8 are the CW switching diodes. With the mode switch in CW position, I have 2.98 volts on the anode of D7 and 2.34 volts on the cathode. I have 10.0 volts on the anode of D8 and 9.40 volts on the cathode. These voltages are there in both RX and TX, just a few 10ths of a volt lower in TX mode.

Can you confirm how the 3 pin cable ofr IF2 is supposed to plug in? It only has 3 wires but there are 5 pins on the IF board at that point. According to the chassis wiring diagram, only the first 3 pins are used as they come from S6-1.

I don't think there is anything wrong with the CW filter and the switching diodes as the CW filter works fine in RX mode.

I have 400mV P-P on Gate 1 of Q1 instead of the 160mV when flipping Send. I also have 2400mV P-P on the drain instead of 1000mV when flipping Send.

TIF signal on Conn IF-3 is 400mV P-P and the sine wave isn't quiet as clean there as it is on the drain of Q1.

Hopefully we are making progress.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Good job. Much better.

If I understand your chart you are telling me that you have approx 640mv P-P @ 8.83077 at TP-5 in CW mode with rig flipped to Send (heaters off and SG switch off). 900mv P-P is attainable by adjusting T1 on CAR-2 board, but can do later unless you want to peak it now. 640mv will work for testing.

If this is true then you have confirmed that you have the two things you need at the Balanced Mod to produce RF output from it in CW mode. 1. Offset bias voltage and 2. Proper Carrier freq and level.

From the BM output the CW signal is routed to the Crystal IF Filter and then to Q1 the Transmit IF Amp or TIF amp. TIF signal leaves the IF board and is routed to the RF board to the TX Mixer where it is mixed with VCO to produce the actual transmit rf drive signal. No TIF signal and there will be no RF drive and no RF output. Also no VCO or low VCO level and no rf drive. Lets validate that we have TIF signal in CW mode first.

Unfortunately KW didnt provide a nice test point at the output of the Balanced Mod to measure the DSBSC signal in SSB mode or the Carrier in CW mode. However, you can get on the Drain of Q10 with a hat pin or floral arrangement pin and mini-grabber test lead. If you locate the BM ring diodes D26-D29 and then output Xfmr T10 you will see Q10. It is a metal can dual gate mosfet. Looking down on the can the Drain is the upper right lead. You should read approx 800mv P-P here. This signal is routed to the Xtal filter thru switcing diodes.

Do you have the CW filter installed. It is rare but could have a bad filter. More common to have a bad switching diode.

After signal passes thru the Xtal filter it is applied to Gate 1 of TIF amp Q1. It is also a metal can dual gate mosfet and sits outside and almost between the two filters at the inboard end. Looking down on Q1 Gate 1 is at 1200. Should have approx 160mv P-P here. The Drain is at 0600 and should have approx 1000mv P-P. TIF output is on Conn IF-3 Pin 2 and should have approx 850mv P-P here. You can jump right to measuring TIF output if you want and if good then off to the RF board.

We know that you have TIF output in FSK mode as you reported good RF output in that mode. I dont kow if you keyed rig in FSK and noted the 170hz shift or not, but not important right now. Also, you should have noted that the RF output in FSK is lower as the 820 lowers the Finals Screen Grid voltage in FSK mode so the tubes plate dissipation is not exceeded in this high duty cycle mode.

That should be enough for now.

Terry K9TW

Topic: 45531 Message: 45534

Greetings.

The mention of keeping a record of various voltages and / or waveforms found in a repaired or never-broken hybrid has come across the board now and again. That it should be done is easy, that's just good sense to do something like that.

Only question I have, and the reason is due to things such as bad diagrams and schematics among other things, is

WHICH voltages/waveforms, at WHAT test points, components, or terminals?

The default settings to use for various controls prior to making any measurements, that I can likely work out (but I would LOVE to hear advice on that as well). Mostly the same ones as are used as defaults for the schematics in the manuals, I would suspect.

Fine, but for one thing - those are "Receive Only" in the Kenwood literature; I would also like a set for Transmit, too. Dummy loaded, of course, and plate / finals properly loaded, too.

And what would change at various points, should measurements be taken on all of the bands the radio has? If so, which ones and what will also be adjusted (besides transmitter finals loading)??

If I can get answers for one radio (I've a TS-520SE, myself, so I'd like to start there if possible) then I can offer to make up a simple spreadsheet, document, form, or something, to record all of these things for troubleshooting later.

Maybe just a simple table or form that can be kept on the computer, or printed, filled in, and stored in the documentation for the equipment? Or keep it in both formats, if you like, one copy each way? My preference, for major convenience' sake, is both ways.

I suspect a LOT of things would be identical from one model to the next. This would make creating a model-specific form fairly simple, too. Once finished, the blank forms/spreadsheets could be stored on the Yahooligan group site, there seems to be plenty of room.

Should I start with the bits I find on the schematics and in the manual for the 520S? (The 520SE seems to be quite left out, documentation-wise. Sort of an "also-ran" a lot of ways. Most things just say "See the docs for the 520S.")

Terry,

Fully agree, I only jumped in because of the comment that no 2nd dip, which supported your comments of a 2nd dip due to the electrical properties of the tuning cap, I knew what you meant about the position of the pointer versus the position of the fins. Will send you some pictures off list to show my findings and supports your comments, albeit the pointer not exactly but the theory was perfect. Only thing I cannot work out is on the 530s one revolution of the dial\pointer is 360 exactly, but there is some form of reduction going on with the pointer, as when you go through different degrees of the pointer it doesn't match the pointer, but not going to get into the discussion until I've pulled the panel apart and done the physics on the drive.

Subject: RE: Re: RE: [TS-520_820_530_830] ts530s tuning

Dave:

You are correct if you started with the plates 100 % open and dip occurred at 10% meshed CW then it would also occur at 10% meshed in the CCW direction and that would be significantly less than 180 degrees. Similarly if you continued to rotate shaft CW back to 10% mesh that would be much more than 180 degrees

Same with 3.5 mhz where plates are 100 % meshed at full CCW as indicated on the painted white arc semi circle travel. So to get back to 100% mesh you would have to turn the cap 360 degrees either direction to get back to max capacitance.

It depends on what band you are on as to how many degrees between the two dips.

I mispoke about the 180 degrees.

Point I am trying to make is the knob pointer will not be 180 degrees from the normal white painted arc dip location when you rotate the shaft and locate the 2nd dip. However at that point you will be at the same electrical point and have the same amount of capacitor plate mesh and the same capacitance to resonate with the particular tank coil tap you have selected with the band switch.

What got me into this discussion was the direction that was given to the Op to rotate the cap 180 degrees or rotate from North to South and he should see the other dip and that is not correct.

I was worried the Op would just turn the Tank cap 180 degrees and key rig in Tune and move knob a few degrees back and forth and find no dip and report back that he only has 1 dip.

☐
Terry,

Just for interest, you said "So each dip is occurring at 180 degrees of rotation which is of course the same amount of plate mesh and capacitance."

Take an example of the cap starting at 0% mesh.
If the dip is found at 10 % mesh cw, the dip will also be found at 10 % mesh ccw with a small angle between them, not 180%.
This leads to two possible cases of one dip per rotation of the cap if:

1) the dip occurs at 100% meshed
or
2) the dip occurs at 0% meshed

What's the probability of case 1 or 2?

Cheers
the other Dave f4eyk

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

With the .047 cap on the anodes of D7 and D8 I am able to obtain full output in CW mode. Also, both diodes are forward biased in CW Send mode as I see approximately .6 volts drop across them in Pos C. The voltages are about .1 volt lower than what you are showing.

Do you know the impedance of the crystal filters in the TS-820? This is the signal source I have to use to test with:
http://www.oocities.org/hagtronics/source/index.html
http://www.oocities.org/hagtronics/source/index.html
It has a 50 ohm output. I also have a HP 3314A I could use but it is also 50 ohms out.

With the signal source set to -1 dB out and in and out connections at the anodes of D7 and D8, I get these are the readings I get:

8.8300 - -46.9 dB
8.8301 - -33.3 dB
8.8302 - -19.5 dB
8.8303 - -14.4 dB
8.8304 - -17.5 dB
8.8305 - -26.4 dB
8.8306 - -28-5 dB
8.8307 - -42.5 dB
8.8308 - -49.5 dB
8.8309 - -49.7 dB
8.8310 - -50.0 dB

The filter FC appears to be at 8.8303. My scope with 1 meg load agrees with this as I see the peak on it at the same frequency. I don't know how much the 50 ohm generator and power meter loads are affecting the filter.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray that is because you have the test cap on the Cathode sides of D7 and D8. Move the cap to the Anode sides of each and the plug to Pos C. Now you are checking the diodes as well.

This test proves that you have sufficient RF carrier level from the BM available at the Cathode of D7 to produce full output in CW.

Problem is if jumpering the filter works then which is bad? The CW filter or one or both diodes or the bias supply to the diodes?

I would focus all my efforts with the plug in Pos C to simplify reading taking.

In Pos C you need to ensure that each diode is forward biased.

D7 Cathode = 2.85vdc
D7 Anode = 2.25vdc

D8 Cathode = 9.8vdc
D8 Anode = 9.2vdc

Pretty sure you have already done this and confirmed you have diode supply voltage and good diodes so that just the filter.

Do you have an RF sig generator? If you do you can sweep the filter. It will tell you couple of things.
1. Where is Fc at (center frequency)
2. What is its attenuation

Doesnt have to be a sophisticated or accurate RF sig gen.

Can set it at around 8.0 mhz as measured by your Simpson Freq counter and set the rf output level to approx 200mv as measured by your O-scope.

Connect the output from RF sig gen to Anode of D7 and your O-scope at Anode of D8 (rig power is off) and slowly raise the frequency and see where the peak RF output voltage occurs at. Should be close to 8830.7khz. This assumes your sig gen output voltage doesnt vary greatly for small change in frequency. If it does you would need two ways to measure RF so you could ride the sig gen output to keep it constant.

Terry K9TW

Terry, with a .047 capacitor across the CW filter, I get full output in CW mode regardless of what position the IF2 connector is in.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

These are the readings taken with IF2 connector in all three positions (P-P values):
Position A: D7 cathode: 800mV CW, 800 mV FSK --- D8 cathode: 600mV CW, 400mV FSK
Position B: D7 cathode: 600mV CW, 800 mV FSK --- D8 cathode: 44mV CW, 400 mV FSK
Position C: D7 cathode: 260mV CW, 800 mv FSK --- D8 cathode: 40mV CW, 400 mV FSK
All readings were taken with my scope with the probe in the 10X position to prevent loading of the circuit.

These are the DC readings for D7 and D8 in all three positions (RMS values):
Position A: CW - D7 anode: -3.6V, cathode: 2.0V -- D8 anode: 0V, cathode: 9.0V
Position A: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode 8.5V
Position B: CW - D7 anode: 2.8V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.7V
Position B: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode: 8.5V
Position C: CW - D7 anode: 2.8V, cathode: 2.2V -- D8 anode: 9.3V, cathode: 8.6V
Position C: FSK - D7 anode: 2.7V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.6V

The only position I get output in CW mode is when the connector is in position A.

The CW filter is a TRIO YG-88C and I have re-soldered all connections on the filter.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

I meant Cathode voltages but I think you get the idea. Measure the Anode and Cathode to ensure both diodes are being switched on. Should see approx 0.65 vdc drop across D7 and D8 as they are silicon diodes.

Not likely bad but if you need to replace I offer the following:

Should you need a diode do not use a NTE 177 sub. These are 1S1587 fast switching diodes with a fast reverse recovery time of approx 2 ns so I would not use a general purpose silicon diode as NTE sub guide suggests. Can use a NTE 519, but it has a recovery time of approx 70 ns.

I think a 1N914 or 1N4148 would be better choice at 4ns..These are still pretty commonly available.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK I forgot to give you the Anode voltages of D7 and D8 but you can just subtract approx 0.65vdc for the turn on voltage.

280mv P-P is high by my measurements, but if you read close to same in FSK-T then call it good. Certainly better than be too low.

6 mv P-P at output in CW-T is definitely a problem. As I said you can jumper the filter with a .047uf cap and see if you get CW Tx.

Is this the factory YG-88C filter?

I believe it has center frequency of 8830.7 mhz.and bandwidth of 500hz at -6dB.
I have never swept one.

It would not seem likely that you would have bad solder connections if the filter is working in FSK mode. Are you 100% certain you are not using the SSB filter in FSK mode?

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

My voltages at D7 and D8 are virtually identical to yours. I had previously measured the levels at D7 and D8. I measured 280mV P-P where C14 connects to the CW filter and only 6mV P-P out of the filter. But that was before I changed the cable to position A. I will have to move the cable back to C and re-measure tomorrow. I will also pull the IF board out and resolder the CW crystal filter connections. It may be bad solder connections as you suggest.

I just made my first contact in 17 years on 7.020 with W5TZC about 30 mins ago. He gave me a 579 which is pretty good considering my antenna is only 8 feet off the ground. I also still have to address why they final isn't tuning properly on 40 meters. It tuned max power with plate knob pointer sitting on the 5 of 3.5. It dips at 14 on 20 meters.

If I can get the CW filter issue worked out I will go through a complete tuneup of the radio following the service manual procedures.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

It is easy to test CW filter switching diodes D7 and D8. I thought you already did this and reported good?

As previously noted my plug is in C all the way toward the front panel.

Conn IF-2 pins 4 and 5 have approx 12.9vdc on them in Rx and Tx for CW-R, CW-T, FSK-R, and FSK-T.

The cathode of D7 is:
CW-R and FSK-R = 2.90vdc
CW-T and FSK- T = 2.90vdc

The cathode of D8 is : (Note: When you connect voltmeter back ground noise will drop significantly).
CW-R and FSK-R = 10.0vdc
CW-T and FSK-T = 9.80vdc

The reading will be different as the diodes are biased to different current levels. You can see the difference in the supply resistors for each diode.

I have never been able to measure TX level diagram RF voltages accurately using a 1X scope probe. It will pull your ALC indication down from FSD (40 over) to approx 25 over.

You should be able to measure the 8.830mhz TIF signal level at the input and output of the CW Xtal filter. I thought we did this a long time ago?

It is normal for the filters to have an insertion loss. Should have a minimum of approx 25mv rms at D7 input and minimum of approx 19mv rms at D8 output.

Here are my RF level measurements at D7 and D8:

Test conditons: 14.175mhz, Heater on , SG switch off, CW mode, Drive control peaked, Car Pot at 2.5 (for full scale ALC deflection or 40 over)

Boonton 92E (using 10x scope probe very close to same levels)
D7 = 58mv

D8 = 25mv

You can jumper across your CW filter with a couple of mini-grabber test leads with a 0.047uf capacitor in series.

Could have good switching diodes and good filter but bad solder connections at the filter?

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I have made a discovery that will probably tell us where the actual problem is. I was googling how to replace CW filter and found this link:
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2

So I downloaded the operators manual and looked at page 34. Kenwood is perfectly clear about this. If the plug is in position A, the CW filter is bypassed.

I put the plug in position A and can tune to full power out in CW mode. If I place the plug in position B or C I get no power out when in CW mode.

Does this indicate a bad CW filter? The filter works fine in receive mode. The only thing I have noticed is that if I switch from USB to CW the signal drops 1 S-unit when peaked for max signal in both modes.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

At this point I am using my scope with 1 meg input. If is become suspicious of the reading I switch the 10X on and take the reading that way.

An immediate problem I see is I only have 10mV P-P at the drain of Q1 in FSK mode and 0 output in CW mode. The diagram says there should be 250 mV rms there. If I pull the CW filter out of the radio, how does the CW transmit work? Does the signal then go through the USB filter or do I need to install a jumper where the CW filter was?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Yes they are RMS.

I take them at around 14.175 to 14.200 mhz with the Car Level pot advanced to the point that with the Drive Control adjusted for a peak in ALC indication at panel meter full scale deflection. Then switch to CW mode and load to approx 100 watts out and turn off SG switch. Leave Car Level and Drive control alone.

Measured values will vary depending on what test instrument you are using, length of any test jumper leads used to access the test points, line voltage.

For example 8.830mhz TIF output at the IF board and input at the RF board is shown as 0.038v. This is 38.0 mv rms rf volts or 38 x 2.828 = 107 mv P-P. So if you have approx 100mv P-P TIF you are good.

Output of the TX Mixer is 1.4v rms or 4.0v P-P. This RF drive level is now 14.175 mhz.

If you plan on doing a lot of this work suggest you invest in a RF Millivolt meter. I use a Boonton 92E. I find it loads the circuits less and just easier and faster to use.

Of coures once you get to the 1.4 volts at output of the TX Mixer the old fashioned RF probe and VTVM works great. Just have to use multi-diode probe at plate of Driver tube and control grids of the Finals. I used a Heath 309C and PK-3 probes and a IM-18 VTVM for years and still have them for fall back.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

Are the transmit levels on page 42 of the service manual correct? Are those RMS values?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Thanks Terry. I have been talking to you since you have been helping. I don't know what made me put Dave on the last message (old age maybe).

I decided to start over from the beginning and go stage by stage this afternoon. This is what I did:
(All measurements taken with Send switch operated and Mode switch in CW position. Also, the measurements are the same in both CW and FSK modes.)

I suspected D1 or L1 was bad on the CAR-II board was bad but that is not the case. I have 720mV on CA2 leaving the CAR-II board in both CW and FSK send modes. I also have 720mV P-P on CA2 (IF5-13) on the IF board. I have 100mV P-P at the coax that connects to C92 on the IF board. On the other end of that coax where it connects to the top of T4 on the IF board I also have 100mV P-P. I would have thought the signal out of Q18 would have been stronger but maybe not.

I have 340mV at the junction of the cathode of D7 and C14 on the IF board. I have 280mV on the side of C14 where it feeds the CW filter. The signal going into the filter measures 8.830755 MHz. I only have 6mV P-P coming out of the crystal filter. Is the crystal filter used for transmit?

I connected the antenna to the radio and 20 meters is open. Tuning in CW signals in USB mode and switching to CW mode drops the signal by about 1 S-Unit when the signal is peaked for max signal in both modes.

Where do I go from here?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Are you talking Dave or Terry ? If someone is helping you off list I can back away as I have a pretty full plate right now.

I am not clear where you are measuring this 40mv P-P signal at?

Before I go I will mention that it is normal to not have a clean sine wave at TIF. It does have harmonic content and it is as you say due to LO mixing action. In this case it is coming from the VCO signal feeding back from the TX Mixer on RF board to the IF board.

This is easy to confirm with a TS-830 as you can easily unplug the VCO cable from the PLL board and the TIF signal will then be a nice clean 8.830mhz sine wave.

Dont worry about the complex waveform. Should still be able to get a reasonably close TIF measurement. It may not match exactly the levels on the TX Level Diagram,but you can compare it to the level you get with FSK carrier oscillator.

I dont use a O-scope to run TX Level diagrams once I get to the output of the TIF amp. I use a Boonton RF Millivolt meter and measure levels in rms and the "dirty" TIF signal presents no problem.

I have a new digital O-scope and it has a variety of digital filters. If I set it for a LP filter with a roll off frequency of 10mhz I can get a pretty clean 8.830 TIF sine wave display.

I dont know the Tek 2445 capability in this regard.

One final reminder is that good TIF signal level of approx 38mv rms or 107mv P-P is based on the premise that you accurately measured CA2 at the iF board of approx 300mv rms or 850mv P-P.

If that signal is not there then you would need to repeat the testing I asked you to do at the Carrier Osc board to confirm the 9vdc CW diode switching voltage is available at D1 and Q2 Buffer amp is being turned on.

I have been providing direction based on your reporting back that you have good CA-2 at Carrier board and good CA-2 at TP-5 on IF board.

If good Level at TP-5 then should have proper level at the wiper of VR-5 on the Balanced Mod. As we have discussed. No dc bias from CV and no Carrier at wiper of VR-5 then no output from the Bal Modulator.

I am pretty confident that you do have proper bias voltage from CCW to full CW on the Car Pot, but I am not certain yet that you have proper carrier output from the BM in CW mode.

Good luck.

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Dave,

I have VFO set to 14.175. With Car pot at 1200, in CW mode I get 40mV P-P in RX mode. When I flip the Send switch, the signal stays at 40 mV but it is no longer a sine wave. It is some kind of more or less sine wave with a lot of noise on it. With the Car pot at max, the

noisy sinewave increases to 60 mV P-P in Send mode.

In FSK mode with Car at 1200 I get 250mV P-P in Send mode. With Car at Max I get 800 mV P-P in Send mode.

At Conn RF1-10 I get 140mV P-P in CW Send mode. I get 800mV P-P in FSK Send mode.

At the mixer output (Q1 and Q8 side of C8) I get 100 mV P-P in CW Send mode. I get 1V P-P in FSK Send mode. The signal at that point is not a sinewave but seems to have multiple signals. Probably some LO feedthrough on the mixer. The frequency counter agrees with the Kendwood readout as 14.1748 MHz.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Sorry about Q10 vs Q18. My fingers work better than what is left of my brain.

The 3 conductor plug should be positioned in forward position toward the front panel.

One thing we did not talk about is whereiyou should have the Car Level Pot set to take these measurements.

The TX Level Diagram is shown in the Service Manual. These levels were taken by Kenwood by loading the rig to approx 100 watts out at 14.175mhz and then turn the SG switch off and leave Car pot alone and Drive control alone.

Since you have no RF output in CW mode I suggest you do this for remainder of the readings:

1. VFO 14.175
2. Peak the Drive Control on receiver noise or the marker signal
3. Car Level Pot 1200
4. Heater on
5. SG switch off
6. Flip to Send to take RF drive levels

So the differences in voltages may be due to where we each have our Car Level pot set at.

Suggest you measure the voltage and frequency of the TIF signal at IF-3 Pin 2 one more time and it should be approx 250mv rms or 700mv P-P @ 8830.7mhz.

If you have close to this time to move on to the RF board. I must say this is getting a little odd as you have good output ini SSB and FSK which tells us you have good TIF level and the TX Mixer on RF Board is working which means you have good VCO (LO to the mixer).

Are you 100% certain you have no CW RF output on all bands? If so, then proceed on to the RF board with Heaters On and SG off and rig peaked as noted above.

You should have close to the values noted on the TX Level Diagram. At Conn RF-1 Pin 10 the 8.830 TIF signal level is approx 38mv rms or 108 P-P.

At output of TX Mixer should have approx 1.5v rms or 4.2v P-P rf drive at MD. At MD frequency will now be 14.175mhz transmit frequency.

If you have no RF drive or very weak at MD then need to measure the VCO level and frequency at RF-1 pin 4 and on board at TP-1. Should be close to 1.0v rms level. If no VCO try on other bands.

We are making good progress. Your Tek 2445 is perfect scope for KW Hybrid work and you apparently know how to use it and can read a schematic and can locate points on these high density boards to take measurements. This really helps.

Based on your report of no RF output in CW mode I would have thought we would have found no TIF sig at output of the IF board. TIF is not band specific and often is caused by no output from the Bal Modulator, This is why I had you start by testing for bias voltage and LO signal available. Never expected that we would be at the RF board and TX Mixer based on good RF output on other modes.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I read a little over 700mV at the drain of Q18 (actually the backside of C92 feeding the coax). I think you meant Q18 instead of Q10.

D7 and D8 are the CW switching diodes. With the mode switch in CW position, I have 2.98 volts on the anode of D7 and 2.34 volts on the cathode. I have 10.0 volts on the anode of D8 and 9.40 volts on the cathode. These voltages are there in both RX and TX, just a few 10ths of a volt lower in TX mode.

Can you confirm how the 3 pin cable ofr IF2 is supposed to plug in? It only has 3 wires but there are 5 pins on the IF board at that point. According to the chassis wiring diagram, only the first 3 pins are used as they come from S6-1.

I don't think there is anything wrong with the CW filter and the switching diodes as the CW filter works fine in RX mode.

I have 400mV P-P on Gate 1 of Q1 instead of the 160mV when flipping Send. I also have 2400mV P-P on the drain instead of 1000mV when flipping Send.

TIF signal on Conn IF-3 is 400mV P-P and the sine wave isn't quiet as clean there as it is on the drain of Q1.

Hopefully we are making progress.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Good job. Much better.

If I understand your chart you are telling me that you have approx 640mv P-P @ 8.83077 at TP-5 in CW mode with rig flipped to Send (heaters off and SG switch off). 900mv P-P is attainable by adjusting T1 on CAR-2 board, but can do later unless you want to peak it now. 640mv will work for testing.

If this is true then you have confirmed that you have the two things you need at the Balanced Mod to produce RF output from it in CW mode. 1. Offset bias voltage and 2. Proper Carrier freq and level.

From the BM output the CW signal is routed to the Crystal IF Filter and then to Q1 the Transmit IF Amp or TIF amp. TIF signal leaves the IF board and is routed to the RF board to the TX Mixer where it is mixed with VCO to produce the actual transmit rf drive signal. No TIF signal and there will be no RF drive and no RF output. Also no VCO or low VCO level and no rf drive. Lets validate that we have TIF signal in CW mode first.

Unfortunately KW didnt provide a nice test point at the output of the Balanced Mod to measure the DSBSC signal in SSB mode or the Carrier in CW mode. However, you can get on the Drain of Q10 with a hat pin or floral arrangement pin and mini-grabber test lead. If you locate the BM ring diodes D26-D29 and then output Xfmr T10 you will see Q10. It is a metal can dual gate mosfet. Looking down on the can the Drain is the upper right lead. You should read approx 800mv P-P here. This signal is routed to the Xtal filter thru switcing diodes.

Do you have the CW filter installed. It is rare but could have a bad filter. More common to have a bad switching diode.

After signal passes thru the Xtal filter it is applied to Gate 1 of TIF amp Q1. It is also a metal can dual gate mosfet and sits outside and almost between the two filters at the inboard end. Looking down on Q1 Gate 1 is at 1200. Should have approx 160mv P-P here. The Drain is at 0600 and should have approx 1000mv P-P. TIF output is on Conn IF-3 Pin 2 and should have approx 850mv P-P here. You can jump right to measuring TIF output if you want and if good then off to the RF board

Dave:

I appreciate your help. Years ago I had Heath and Johnson rigs and they used Jackson drives for the VFO air variable caps. National also made Vernier drives. I never took one apart to see how they worked. I seem to recall most were 6 to 1 and 5 to 1 ratios. Jackson had ball bearings in them and people would take them apart and clean and re-assemble them.

No need to go to all that trouble unless you just have burning desire to see how it works. Appears it is a small package device.

We just need to get the Op to make sure his shaft couplers are all tight, the pointer is at far left side of the white arc when cap plates are fully meshed, and then run thru full 360 degrees in Tune mode to find both dips.

I know of no way that there can be only one dip if the cap is actually turning 360 degrees from full closed to full closed again. I suppose if there was plate damage at some point in that travel that shorted the plates at that location, but I would think that would be very noticeable as you traveled thru that location?

Dave:

You are correct if you started with the plates 100 % open and dip occurred at 10% meshed CW then it would also occur at 10% meshed in the CCW direction and that would be significantly less than 180 degrees. Similarly if you continued to rotate shaft CW back to 10% mesh that would be much more than 180 degrees

Same with 3.5 mhz where plates are 100 % meshed at full CCW as indicated on the painted white arc semi circle travel. So to get back to 100% mesh you would have to turn the cap 360 degrees either direction to get back to max capacitance.

It depends on what band you are on as to how many degrees between the two dips.

I mispoke about the 180 degrees.

Point I am trying to make is the knob pointer will not be 180 degrees from the normal white painted arc dip location when you rotate the shaft and locate the 2nd dip. However at that point you will be at the same electrical point and have the same amount of capacitor plate mesh and the same capacitance to resonate with the particular tank coil tap you have selected with the band switch.

What got me into this discussion was the direction that was given to the Op to rotate the cap 180 degrees or rotate from North to South and he should see the other dip and that is not correct.

I was worried the Op would just turn the Tank cap 180 degrees and key rig in Tune and move knob a few degrees back and forth and find no dip and report back that he only has 1 dip.

☐ Terry,

Just for interest, you said "So each dip is occurring at 180 degrees of rotation which is of course the same amount of plate mesh and capacitance."
Take an example of the cap starting at 0% mesh.
If the dip is found at 10 % mesh cw, the dip will also be found at 10 % mesh ccw with a small angle between them, not 180%.
This leads to two possible cases of one dip per rotation of the cap if:

1) the dip occurs at 100% meshed
or
2) the dip occurs at 0% meshed

What's the probability of case 1 or 2?

Subject: RE: RE: [TS-520_820_530_830] ts530s tuning

Dave

Thanks. Now can you please explain to us all how a air variable capacitor that can turn physically 360 degrees and be direct drive driven can have 2 dips that are not very close to 180 degrees using the knob pointer as an indicator? What I see is the actual fins are about 180 opposite phase, whilst this doesnt corrolate directly to pointer due to some form of reduction drive, the physical aspects are as you stated. The same amount of fins are being meshed just on the opposite side

If you remove the PA cage cover what will you see?

Are the plates meshed exactly same amount at each dip only on the opposite side of the rotation ie at the normal scribed dip the plates are meshed toward the load cap and at the 2nd dip at the 1700 pointer position the plates are meshed on the final tube side?

Do we have a cap that has a different linearity curve from one side to the other?

Or is there some kind of reduction device on the pointer?

I submit (despite being told there is no reduction drive) that there is some type of reduction device on the front panel behind the knob that drives the capacitor and pointer. If you look at the knob it should have a slit in it. If it does not then make a lite mark on it or affix piece of tape on it. Now turn the knob and take the pointer thru 360 degrees of rotation and count the number of times the knob travels 360 degrees. You should find it is a ratio somewhere between 5 to 1 and 6 to 1. On the TS-830 it is 5.5 to 1 reduction. You could also mark the fiber coupler at the PA cage and count turns or take the PA cage cover off.

That makes a lot more sense than building an air variable cap with a different linearity curve on opposite sides of rotation.

So each dip is occurring at 180 degrees of rotation which is of course the same amount of plate mesh and capacitance. The pointer is just not at 180 degrees for each dip due to the drive ratio.

So Dave if you get time appreciate you putting this mystery to bed.

To the Op I submit he does have two dips and he just needs to do a complete 360 degree rotation in Tune mode to find both of them as I previously suggested. To best of my knowledge there is no padder cap used on the Tank capacitor on 20 meters that if bad could affect the normal plate dip location.

After looking at the diagram, yes concur that there is no addition capacitance from the padder caps, what is seen is VC2 part 2 of the air cap comes into play, this adds extra capacitance. Now with this information is it possible that there is a slight difference due to a previous arching issue, are the fins slightly out of alignment.

Wes

You already have the dc voltages in Rx and Tx mode for the active devices (DSG and CBE). and you have the TX Level Diagram that shows the RF voltage levels from the Bal Mod to the Finals control grids and the RX Level Diagrams that show what RF sig gen levels you must inject for a constant 50 milliwatt output. .

Problem is getting access to the device leads on component side of the board. TS-820 is probably the easiest as a little less dense and devices are spaced a little higher off the board.

Also some of the values listed are not correct. S-,meter driver comes to mind as you need to run RF gain thru its range and record the dc voltage at full ccw and at full cw.

Of course would be good to record DC and Signal voltages for a rig that is working to factory spec in Rx and Tx modes. Problem is how do you know it is aligned to spec absent some decent test gear. Can use Marker and S-meter as rough indication of performance or if you are happy based on your ear. .

It is also good to record the dc voltages at all the Mixer devices and the goes in and goes out signal voltages (IF, RF, and LO signal levels).

Another handy bit of info is to record all the power supply voltages under load, record the normal load current (requires lifting the load leads and inserting milli ampere meter in circuit), and/or recording the normal resistance to ground that each supply feeds. This comes in very handy trouble shooting the Rect boards and AVR boards.

If you have a rig that you are happy with its Rx and Tx performance you could run Rx and Tx level diagrams and record your results. However, you already have the base line data in the Service manual for this if you have a future need.

One thing I do notice is people struggle taking TX Level Diagrams to troubleshoot low or missing RF output. For that reason I think a more gainful exercise for any Hybrid owner who does own repair would be to run the TX Level diagrams when your rig is producing spec RF output into dummy load.. Do that and record your as found levels for future transmit problems.

I suggest you should do this to learn where the test points are at and how you can access them and how your RF measuring instrumentation will affect the results that you get.

How to use the RF measuring Instruments and instrument effect is a common problem that results in readings that vary from the service manual readings and confuses folks and causes them to go down wrong paths..

Greetings.

The mention of keeping a record of various voltages and / or waveforms found in a repaired or never-broken hybrid has come across the board now and again. That it should be done is easy, that's just good sense to do something like that.

Only question I have, and the reason is due to things such as bad diagrams and schematics among other things, is

WHICH voltages/waveforms, at WHAT test points, components, or terminals?

The default settings to use for various controls prior to making any measurements, that I can likely work out (but I would LOVE to hear advice on that as well). Mostly the same ones as are used as defaults for the schematics in the manuals, I would suspect.

Fine, but for one thing - those are "Receive Only" in the Kenwood literature; I would also like a set for Transmit, too. Dummy loaded, of course, and plate / finals properly loaded, too.

And what would change at various points, should measurements be taken on all of the bands the radio has? If so, which ones and what will also be adjusted (besides transmitter finals loading)??

If I can get answers for one radio (I've a TS-520SE, myself, so I'd like to start there if possible) then I can offer to make up a simple spreadsheet, document, form, or something, to record all of these things for troubleshooting later.

Maybe just a simple table or form that can be kept on the computer, or printed, filled in, and stored in the documentation for the equipment? Or keep it in both formats, if you like, one copy each way? My preference, for major convenience' sake, is both ways.

I suspect a LOT of things would be identical from one model to the next. This would make creating a model-specific form fairly simple, too. Once finished, the blank forms/spreadsheets could be stored on the Yahooligan group site, there seems to be plenty of room.

Should I start with the bits I find on the schematics and in the manual for the 520S? (The 520SE seems to be quite left out, documentation-wise. Sort of an "also-ran" a lot of ways. Most things just say "See the docs for the 520S.")

OK I thought I read about problems with 100k resistors on a "board" ?

Ron:

This is a very simple classic two resistor voltage divider. Couple of ways to provide a lower dc voltage from a higher dc voltage. 1. Use a series dropping resistor Or 2. Use a voltage divider. Series resistor method has poor regulation so can improve upon that somewhat by using a divider. ARRL Handbook under AC Power Supplies chapter describes Voltage Dividers and the associated calcs.

You need approx 105vdc for STB so KW takes two 100k ohm resistors and places them in series. At free end of 1st resistor R16 connect 210vdc and at free end of the 2nd resistor R17 connect it to chassis ground. Now at the center of the two the voltage divides in half. Current with no load connected to the center would be I= E/R or 210/200k = 1ma. So very little power is being dissipated by these resistors and they should never over heat or change value over time enough to present a 198 ohm short on your 210A supply.

In practice STB presents approx 600k load across the 2nd 100k resistor R17 so the equivalent resistance of R17 is 600 x 100/700 = 86k ohms. So the voltage does not divide exactly in half but very close.

You can lift the 210vdc lead off top of R16 and lift the 105vdc (STB feed) lead off the center and then measure the resistance of each 100k resistor.

It would be extremely rare for these resistors not to measure very close to 100k each.

More likely problem would be a carbon track on the back side of the phenolic terminal strip that would be out of your view. That track would almost have to be at the top of R16 to ground. Not a very likely failure.

You can also measure resistance of the lifted STB lead.

Pretty sure I suggested that you make these measurements some time ago?

If you lift the 210 feed off of R16 do you now get normal screen grid voltage on the finals and driver tube and no overheating of R6 470 ohm series resistor?

Ron:

If the two 100k ohm divider resistors that feed STB are on the rectifier board then you have a TS520S and not a TS520. I thought we were working on a TS-520? I decided to post as your response came on Gordons thread about contesting?

Did you have a carbon track to board ground plane or what was the failure on the board? Did you swap boards or make a repair?

I assume R6 470 ohm is no longer smoking and you have good 210A screen grid voltage for the finals and the driver tube?

Dave:

As to 5ma initial dip that is another reason why I recommend new folks use an external wattmeter. The initial peak in RF output power on a wattmeter is much more discernable than the initial plate current dip. I also tell them to make sure that the Plate Load cap plates are fully meshed (full CCW on the TS530) so they can see this small dip. Of course after getting the initial dip then go to CW mode and now with full SG voltage applied will be able to see the dip much easier.

After they make that initial dip if they follow the operating manual instructions they will use relative RF output power to load the rig and not be concerned about plate current dip.

So in Tune mode the OP needs to make sure the Plate Load cap is full CCW and then rotate the Plate Tune cap thru its complete range to locate both dips.

I had not thought about that he might have the Plate load cap plates unmeshed.

We just need to get the Op to make sure his shaft couplers are all tight, the pointer is at far left side of the white arc when cap plates are fully meshed, and then run thru full 360 degrees in Tune mode to find both dips.

I know of no way that there can be only one dip if the cap is actually turning 360 degrees from full closed to full closed again. I suppose if there was plate damage at some point in that travel that shorted the plates at that location, but I would think that would be very noticeable as you traveled thru that location?

Terry,

Fully agree, I only jumped in because of the comment that no 2nd dip, which supported your comments of a 2nd dip due to the electrical properties of the tuning cap, I knew what you meant about the position of the pointer versus the position of the fins. Will send you some pictures off list to show my findings and supports your comments, albeit the pointer not exactly but the theory was perfect. Only thing I cannot work out is on the 530s one revolution of the dial\pointer is 360 exactly, but there is some form of reduction going on with the pointer, as when you go through different degrees of the pointer it doesn't match the pointer, but not going to get into the discussion until I've pulled the panel apart and done the physics on the drive.

Subject: RE: Re: RE: [TS-520_820_530_830] ts530s tuning

Dave:

You are correct if you started with the plates 100 % open and dip occurred at 10% meshed CW then it would also occur at 10% meshed in the CCW direction and that would be significantly less than 180 degrees. Similarly if you continued to rotate shaft CW back to 10% mesh that would be much more than 180 degrees

Same with 3.5 mhz where plates are 100 % meshed at full CCW as indicated on the painted white arc semi circle travel. So to get back to 100% mesh you would have to turn the cap 360 degrees either direction to get back to max capacitance.

It depends on what band you are on as to how many degrees between the two dips.

I mispoke about the 180 degrees.

Point I am trying to make is the knob pointer will not be 180 degrees from the normal white painted arc dip location when you rotate the shaft and locate the 2nd dip. However at that

point you will be at the same electrical point and have the same amount of capacitor plate mesh and the same capacitance to resonate with the particular tank coil tap you have selected with the band switch.

What got me into this discussion was the direction that was given to the Op to rotate the cap 180 degrees or rotate from North to South and he should see the other dip and that is not correct.

I was worried the Op would just turn the Tank cap 180 degrees and key rig in Tune and move knob a few degrees back and forth and find no dip and report back that he only has 1 dip.

☐ Terry,

Just for interest, you said "So each dip is occurring at 180 degrees of rotation which is of course the same amount of plate mesh and capacitance."
Take an example of the cap starting at 0% mesh.
If the dip is found at 10 % mesh cw, the dip will also be found at 10 % mesh ccw with a small angle between them, not 180%.
This leads to two possible cases of one dip per rotation of the cap if:

1) the dip occurs at 100% meshed
or
2) the dip occurs at 0% meshed

What's the probability of case 1 or 2?

Cheers

Topic: 45375 Message: 45544

Terry,

Let me try again. The unreadable post has been happening a lot since Yahoo went to this new format last month.

With the .047 cap on the anodes of D7 and D8 I am able to obtain full output in CW mode. Also, both diodes are forward biased in CW Send mode as I see approximately .6 volts drop across them in Pos C. The voltages are about .1 volt lower than what you are showing.

Do you know the impedance of the crystal filters in the TS-820? This is the signal source I have to use to test with:
http://www.oocities.org/hagtronics/source/index.html
It has a 50 ohm output. I also have a HP 3314A I could use but it is also 50 ohms out.

With the signal source set to -1 dB out and in and out connections at the anodes of D7 and D8, I get these are the readings I get:
8.8300 - -46.9 dB
8.8301 - -33.3 dB
8.8302 - -19.5 dB
8.8303 - -14.4 dB
8.8304 - -17.5 dB
8.8305 - -26.4 dB
8.8306 - -28-5 dB
8.8307 - -42.5 dB
8.8308 - -49.5 dB
8.8309 - -49.7 dB
8.8310 - -50.0 dB

The filter FC appears to be at 8.8303. My scope with 1 meg load agrees with this as I see the peak on it at the same frequency. I don't know how much the 50 ohm generator and power meter loads are affecting the filter.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray that is because you have the test cap on the Cathode sides of D7 and D8. Move the cap to the Anode sides of each and the plug to Pos C. Now you are checking the diodes as well.

This test proves that you have sufficient RF carrier level from the BM available at the Cathode of D7 to produce full output in CW.

Problem is if jumpering the filter works then which is bad? The CW filter or one or both diodes or the bias supply to the diodes?

I would focus all my efforts with the plug in Pos C to simplify reading taking.

In Pos C you need to ensure that each diode is forward biased.

D7 Cathode = 2.85vdc
D7 Anode = 2.25vdc

D8 Cathode = 9.8vdc
D8 Anode = 9.2vdc

Pretty sure you have already done this and confirmed you have diode supply voltage and good diodes so that just the filter.

Do you have an RF sig generator? If you do you can sweep the filter. It will tell you couple of things.
1. Where is Fc at (center frequency)
2. What is its attenuation

Doesnt have to be a sophisticated or accurate RF sig gen.

Can set it at around 8.0 mhz as measured by your Simpson Freq counter and set the rf output level to approx 200mv as measured by your O-scope.

Connect the output from RF sig gen to Anode of D7 and your O-scope at Anode of D8 (rig power is off) and slowly raise the frequency and see where the peak RF output voltage occurs at. Should be close to 8830.7khz. This assumes your sig gen output voltage doesnt vary greatly for small change in frequency. If it does you would need two ways to measure RF so you could ride the sig gen output to keep it constant.

Terry K9TW

Terry, with a .047 capacitor across the CW filter, I get full output in CW mode regardless of what position the IF2 connector is in.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

These are the readings taken with IF2 connector in all three positions (P-P values):
Position A: D7 cathode: 800mV CW, 800 mV FSK --- D8 cathode: 600mV CW, 400mV FSK
Position B: D7 cathode: 600mV CW, 800 mV FSK --- D8 cathode: 44mV CW, 400 mV FSK
Position C: D7 cathode: 260mV CW, 800 mv FSK --- D8 cathode: 40mV CW, 400 mV FSK
All readings were taken with my scope with the probe in the 10X position to prevent loading of the circuit.

These are the DC readings for D7 and D8 in all three positions (RMS values):
Position A: CW - D7 anode: -3.6V, cathode: 2.0V -- D8 anode: 0V, cathode: 9.0V
Position A: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode 8.5V
Position B: CW - D7 anode: 2.8V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.7V
Position B: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode: 8.5V
Position C: CW - D7 anode: 2.8V, cathode: 2.2V -- D8 anode: 9.3V, cathode: 8.6V
Position C: FSK - D7 anode: 2.7V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.6V

The only position I get output in CW mode is when the connector is in position A.

The CW filter is a TRIO YG-88C and I have re-soldered all connections on the filter.

I meant Cathode voltages but I think you get the idea. Measure the Anode and Cathode to ensure both diodes are being switched on. Should see approx 0.65 vdc drop across D7 and D8 as they are silicon diodes.

Not likely bad but if you need to replace I offer the following:

Should you need a diode do not use a NTE 177 sub. These are 1S1587 fast switching diodes with a fast reverse recovery time of approx 2 ns so I would not use a general purpose silicon diode as NTE sub guide suggests. Can use a NTE 519, but it has a recovery time of approx 70 ns.

I think a 1N914 or 1N4148 would be better choice at 4ns..These are still pretty commonly available.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK I forgot to give you the Anode voltages of D7 and D8 but you can just subtract approx 0.65vdc for the turn on voltage.

280mv P-P is high by my measurements, but if you read close to same in FSK-T then call it good. Certainly better than be too low.

6 mv P-P at output in CW-T is definitely a problem. As I said you can jumper the filter with a .047uf cap and see if you get CW Tx.

Is this the factory YG-88C filter?

I believe it has center frequency of 8830.7 mhz.and bandwidth of 500hz at -6dB.
I have never swept one.

It would not seem likely that you would have bad solder connections if the filter is working in FSK mode. Are you 100% certain you are not using the SSB filter in FSK mode?

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

My voltages at D7 and D8 are virtually identical to yours. I had previously measured the levels at D7 and D8. I measured 280mV P-P where C14 connects to the CW filter and only 6mV P-P out of the filter. But that was before I changed the cable to position A. I will have to move the cable back to C and re-measure tomorrow. I will also pull the IF board out and resolder the CW crystal filter connections. It may be bad solder connections as you suggest.

I just made my first contact in 17 years on 7.020 with W5TZC about 30 mins ago. He gave me a 579 which is pretty good considering my antenna is only 8 feet off the ground. I also still have to address why they final isn't tuning properly on 40 meters. It tuned max power with plate knob pointer sitting on the 5 of 3.5. It dips at 14 on 20 meters.

If I can get the CW filter issue worked out I will go through a complete tuneup of the radio following the service manual procedures.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

It is easy to test CW filter switching diodes D7 and D8. I thought you already did this and reported good?

As previously noted my plug is in C all the way toward the front panel.

Conn IF-2 pins 4 and 5 have approx 12.9vdc on them in Rx and Tx for CW-R, CW-T, FSK-R, and FSK-T.

The cathode of D7 is:
CW-R and FSK-R = 2.90vdc
CW-T and FSK- T = 2.90vdc

The cathode of D8 is : (Note: When you connect voltmeter back ground noise will drop significantly).
CW-R and FSK-R = 10.0vdc
CW-T and FSK-T = 9.80vdc

The reading will be different as the diodes are biased to different current levels. You can see the difference in the supply resistors for each diode.

I have never been able to measure TX level diagram RF voltages accurately using a 1X scope probe. It will pull your ALC indication down from FSD (40 over) to approx 25 over.

You should be able to measure the 8.830mhz TIF signal level at the input and output of the CW Xtal filter. I thought we did this a long time ago?

It is normal for the filters to have an insertion loss. Should have a minimum of approx 25mv rms at D7 input and minimum of approx 19mv rms at D8 output.

Here are my RF level measurements at D7 and D8:

Test conditons: 14.175mhz, Heater on , SG switch off, CW mode, Drive control peaked, Car Pot at 2.5 (for full scale ALC deflection or 40 over)

Boonton 92E (using 10x scope probe very close to same levels)
D7 = 58mv
D8 = 25mv

You can jumper across your CW filter with a couple of mini-grabber test leads with a 0.047uf capacitor in series.

Could have good switching diodes and good filter but bad solder connections at the filter?

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I have made a discovery that will probably tell us where the actual problem is. I was googling how to replace CW filter and found this link:
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2

So I downloaded the operators manual and looked at page 34. Kenwood is perfectly clear about this. If the plug is in position A, the CW filter is bypassed.

I put the plug in position A and can tune to full power out in CW mode. If I place the plug in position B or C I get no power out when in CW mode.

Does this indicate a bad CW filter? The filter works fine in receive mode. The only thing I have noticed is that if I switch from USB to CW the signal drops 1 S-unit when peaked for max signal in both modes.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

At this point I am using my scope with 1 meg input. If is become suspicious of the reading I switch the 10X on and take the reading that way.

An immediate problem I see is I only have 10mV P-P at the drain of Q1 in FSK mode and 0 output in CW mode. The diagram says there should be 250 mV rms there. If I pull the CW filter out of the radio, how does the CW transmit work? Does the signal then go through the USB filter or do I need to install a jumper where the CW filter was?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Yes they are RMS.

I take them at around 14.175 to 14.200 mhz with the Car Level pot advanced to the point that with the Drive Control adjusted for a peak in ALC indication at panel meter full scale deflection. Then switch to CW mode and load to approx 100 watts out and turn off SG switch. Leave Car Level and Drive control alone.

Measured values will vary depending on what test instrument you are using, length of any test jumper leads used to access the test points, line voltage.

For example 8.830mhz TIF output at the IF board and input at the RF board is shown as 0.038v. This is 38.0 mv rms rf volts or 38 x 2.828 = 107 mv P-P. So if you have approx 100mv P-P TIF you are good.

Output of the TX Mixer is 1.4v rms or 4.0v P-P. This RF drive level is now 14.175 mhz.

If you plan on doing a lot of this work suggest you invest in a RF Millivolt meter. I use a Boonton 92E. I find it loads the circuits less and just easier and faster to use.

Of coures once you get to the 1.4 volts at output of the TX Mixer the old fashioned RF probe and VTVM works great. Just have to use multi-diode probe at plate of Driver tube and control grids of the Finals. I used a Heath 309C and PK-3 probes and a IM-18 VTVM for years and still have them for fall back.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Thanks Terry. I have been talking to you since you have been helping. I don't know what made me put Dave on the last message (old age maybe).

I decided to start over from the beginning and go stage by stage this afternoon. This is what I did:
(All measurements taken with Send switch operated and Mode switch in CW position. Also, the measurements are the same in both CW and FSK modes.)

I suspected D1 or L1 was bad on the CAR-II board was bad but that is not the case. I have 720mV on CA2 leaving the CAR-II board in both CW and FSK send modes. I also have 720mV P-P on CA2 (IF5-13) on the IF board. I have 100mV P-P at the coax that connects to C92 on the IF board. On the other end of that coax where it connects to the top of T4 on the IF board I also have 100mV P-P. I would have thought the signal out of Q18 would have been stronger but maybe not.

I have 340mV at the junction of the cathode of D7 and C14 on the IF board. I have 280mV on the side of C14 where it feeds the CW filter. The signal going into the filter measures 8.830755 MHz. I only have 6mV P-P coming out of the crystal filter. Is the crystal filter used for transmit?

I connected the antenna to the radio and 20 meters is open. Tuning in CW signals in USB mode and switching to CW mode drops the signal by about 1 S-Unit when the signal is peaked for max signal in both modes.

Where do I go from here?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Are you talking Dave or Terry ? If someone is helping you off list I can back away as I have a pretty full plate right now.

I am not clear where you are measuring this 40mv P-P signal at?

Before I go I will mention that it is normal to not have a clean sine wave at TIF. It does have harmonic content and it is as you say due to LO mixing action. In this case it is coming from the VCO signal feeding back from the TX Mixer on RF board to the IF board.

This is easy to confirm with a TS-830 as you can easily unplug the VCO cable from the PLL board and the TIF signal will then be a nice clean 8.830mhz sine wave.

Dont worry about the complex waveform. Should still be able to get a reasonably close TIF measurement. It may not match exactly the levels on the TX Level Diagram,but you can compare it to the level you get with FSK carrier oscillator.

I dont use a O-scope to run TX Level diagrams once I get to the output of the TIF amp. I use a Boonton RF Millivolt meter and measure levels in rms and the "dirty" TIF signal presents no problem.

I have a new digital O-scope and it has a variety of digital filters. If I set it for a LP filter with a roll off frequency of 10mhz I can get a pretty clean 8.830 TIF sine wave display.

I dont know the Tek 2445 capability in this regard.

One final reminder is that good TIF signal level of approx 38mv rms or 107mv P-P is based on the premise that you accurately measured CA2 at the iF board of approx 300mv rms or 850mv P-P.

If that signal is not there then you would need to repeat the testing I asked you to do at the Carrier Osc board to confirm the 9vdc CW diode switching voltage is available at D1 and Q2 Buffer amp is being turned on.

I have been providing direction based on your reporting back that you have good CA-2 at Carrier board and good CA-2 at TP-5 on IF board.

If good Level at TP-5 then should have proper level at the wiper of VR-5 on the Balanced Mod. As we have discussed. No dc bias from CV and no Carrier at wiper of VR-5 then no output from the Bal Modulator.

I am pretty confident that you do have proper bias voltage from CCW to full CW on the Car Pot, but I am not certain yet that you have proper carrier output from the BM in CW mode.

Good luck.

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Dave,

I have VFO set to 14.175. With Car pot at 1200, in CW mode I get 40mV P-P in RX mode. When I flip the Send switch, the signal stays at 40 mV but it is no longer a sine wave. It is some kind of more or less sine wave with a lot of noise on it. With the Car pot at max, the noisy sinewave increases to 60 mV P-P in Send mode.

In FSK mode with Car at 1200 I get 250mV P-P in Send mode. With Car at Max I get 800 mV P-P in Send mode.

At Conn RF1-10 I get 140mV P-P in CW Send mode. I get 800mV P-P in FSK Send mode.

At the mixer output (Q1 and Q8 side of C8) I get 100 mV P-P in CW Send mode. I get 1V P-P in FSK Send mode. The signal at that point is not a sinewave but seems to have multiple signals. Probably some LO feedthrough on the mixer. The frequency counter agrees with the Kendwood readout as 14.1748 MHz.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Sorry about Q10 vs Q18. My fingers work better than what is left of my brain.

The 3 conductor plug should be positioned in forward position toward the front panel.

One thing we did not talk about is whereiyou should have the Car Level Pot set to take these measurements.

The TX Level Diagram is shown in the Service Manual. These levels were taken by Kenwood by loading the rig to approx 100 watts out at 14.175mhz and then turn the SG switch off and leave Car pot alone and Drive control alone.

Since you have no RF output in CW mode I suggest you do this for remainder of the readings:

1. VFO 14.175
2. Peak the Drive Control on receiver noise or the marker signal
3. Car Level Pot 1200
4. Heater on
5. SG switch off
6. Flip to Send to take RF drive levels

So the differences in voltages may be due to where we each have our Car Level pot set at.

Suggest you measure the voltage and frequency of the TIF signal at IF-3 Pin 2 one more time and it should be approx 250mv rms or 700mv P-P @ 8830.7mhz.

If you have close to this time to move on to the RF board. I must say this is getting a little odd as you have good output ini SSB and FSK which tells us you have good TIF level and the TX Mixer on RF Board is working which means you have good VCO (LO to the mixer).

Are you 100% certain you have no CW RF output on all bands? If so, then proceed on to the RF board with Heaters On and SG off and rig peaked as noted above.

You should have close to the values noted on the TX Level Diagram. At Conn RF-1 Pin 10 the 8.830 TIF signal level is approx 38mv rms or 108 P-P.

At output of TX Mixer should have approx 1.5v rms or 4.2v P-P rf drive at MD. At MD frequency will now be 14.175mhz transmit frequency.

If you have no RF drive or very weak at MD then need to measure the VCO level and frequency at RF-1 pin 4 and on board at TP-1. Should be close to 1.0v rms level. If no VCO try on other bands.

We are making good progress. Your Tek 2445 is perfect scope for KW Hybrid work and you apparently know how to use it and can read a schematic and can locate points on these high density boards to take measurements. This really helps.

Based on your report of no RF output in CW mode I would have thought we would have found no TIF sig at output of the IF board. TIF is not band specific and often is caused by no output from the Bal Modulator, This is why I had you start by testing for bias voltage and LO signal available. Never expected that we would be at the RF board and TX Mixer based on good RF output on other modes.

Terry K9TW

Terry,

I read a little over 700mV at the drain of Q18 (actually the backside of C92 feeding the coax). I think you meant Q18 instead of Q10.

D7 and D8 are the CW switching diodes. With the mode switch in CW position, I have 2.98 volts on the anode of D7 and 2.34 volts on the cathode. I have 10.0 volts on the anode of D8 and 9.40 volts on the cathode. These voltages are there in both RX and TX, just a few 10ths of a volt lower in TX mode.

Can you confirm how the 3 pin cable ofr IF2 is supposed to plug in? It only has 3 wires but there are 5 pins on the IF board at that point. According to the chassis wiring diagram, only the first 3 pins are used as they come from S6-1.

I don't think there is anything wrong with the CW filter and the switching diodes as the CW filter works fine in RX mode.

I have 400mV P-P on Gate 1 of Q1 instead of the 160mV when flipping Send. I also have 2400mV P-P on the drain instead of 1000mV when flipping Send.

TIF signal on Conn IF-3 is 400mV P-P and the sine wave isn't quiet as clean there as it is on the drain of Q1.

Hopefully we are making progress.

Ray:

Good job. Much better.

If I understand your chart you are telling me that you have approx 640mv P-P @ 8.83077 at TP-5 in CW mode with rig flipped to Send (heaters off and SG switch off). 900mv P-P is attainable by adjusting T1 on CAR-2 board, but can do later unless you want to peak it now. 640mv will work for testing.

If this is true then you have confirmed that you have the two things you need at the Balanced Mod to produce RF output from it in CW mode. 1. Offset bias voltage and 2. Proper Carrier freq and level.

From the BM output the CW signal is routed to the Crystal IF Filter and then to Q1 the Transmit IF Amp or TIF amp. TIF signal leaves the IF board and is routed to the RF board to the TX Mixer where it is mixed with VCO to produce the actual transmit rf drive signal. No TIF signal and there will be no RF drive and no RF output. Also no VCO or low VCO level and no rf drive. Lets validate that we have TIF signal in CW mode first.

45545. MC-60 mic issues

Hi,
I have an MC-60 mic that works great except for the lock button for transmit. It appears that a previous owner must have removed the mechanical linkage that makes the lock work. Does anyone have pictures of this mechanism or a link of where to get this part?

Thanks and 73's

I'm new to the Kenwood Hybrid. I've been reading quite a bit about them, and one thing in particular I find is there are so many different ways people tune the transceiver. I was wondering if anyone here could recommend a YouTube video that demonstrates the best way to tune the hybrid for transmit. I've found a few YouTube videos. None of them seem to follow the manual when tuning.

Ray

Much better got it all this time.

Yes the diode barrier voltages will vary as the dc supply and line voltage will also vary. As long at the diodes are the original silicon diodes then 0.6vdc to 0.7vdc is typical. You are looking for gross differences between what I read. I looked at your readings and I agree the diodes are fine and the switching voltage supply to them is there.

Yes for most accurate sweep should terminate filter input and output in its characteristic impedance, but for this test what you have should be OK as we are only interested in relative rf voltages. I dont know what the input/output impedance of this filter is. Most of the KW filters have impedances that range from 300 ohms to 2k ohms that I have seen. You could experiment and repeat test with resistor divider on each end.

When I sweep a KW filter out of the rig on the bench I look at service manual for the input/output impedance. I then make a 2 resistor divider at each side of the filter. For example if the filter Z is 600 ohms I will place a 600 ohm resistor in series with the filter input and a 50 ohm resistor in shunt to ground. I connect the sig gen to the free end of the 600 ohm series resistor. Do same at output and connect the O-scope or RF millivolt meter to the free end of the 600 ohm resistor.

You can see that if your CW TX carrier frequency is 8830.7 as it should be then it will be outside the -6dB bandpass of the filter if the measured FC is 8830.3.

I will try to get time tomorrow and sweep my filter in place using same method you employed for comparison.

What you know for sure is :
1. D7/D8 are being biased on in CW mode.
2. With .047 cap bridging the filter you get full RF output in CW mode
3. With cap removed no RF output

Sure looks like filter is the culprit.

You are doing some good work here. Absent test gear, knowing how to use it, ability to read a schematic, and some familiarization with the board layouts this is a challenging task for any hybrid owner.

I will get back with my sweep results.

Terry K9TW

Terry,

Let me try again. The unreadable post has been happening a lot since Yahoo went to this new format last month.

With the .047 cap on the anodes of D7 and D8 I am able to obtain full output in CW mode. Also, both diodes are forward biased in CW Send mode as I see approximately .6 volts drop across them in Pos C. The voltages are about .1 volt lower than what you are showing.

Do you know the impedance of the crystal filters in the TS-820? This is the signal source I have to use to test with:
http://www.oocities.org/hagtronics/source/index.html
It has a 50 ohm output. I also have a HP 3314A I could use but it is also 50 ohms out.

With the signal source set to -1 dB out and in and out connections at the anodes of D7 and D8, I get these are the readings I get:
8.8300 - -46.9 dB
8.8301 - -33.3 dB
8.8302 - -19.5 dB
8.8303 - -14.4 dB
8.8304 - -17.5 dB
8.8305 - -26.4 dB
8.8306 - -28-5 dB
8.8307 - -42.5 dB
8.8308 - -49.5 dB
8.8309 - -49.7 dB
8.8310 - -50.0 dB

The filter FC appears to be at 8.8303. My scope with 1 meg load agrees with this as I see the peak on it at the same frequency. I don't know how much the 50 ohm generator and power meter loads are affecting the filter.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray that is because you have the test cap on the Cathode sides of D7 and D8. Move the cap to the Anode sides of each and the plug to Pos C. Now you are checking the diodes as well.

This test proves that you have sufficient RF carrier level from the BM available at the Cathode of D7 to produce full output in CW.

Problem is if jumpering the filter works then which is bad? The CW filter or one or both diodes or the bias supply to the diodes?

I would focus all my efforts with the plug in Pos C to simplify reading taking.

In Pos C you need to ensure that each diode is forward biased.

D7 Cathode = 2.85vdc
D7 Anode = 2.25vdc

D8 Cathode = 9.8vdc
D8 Anode = 9.2vdc

Pretty sure you have already done this and confirmed you have diode supply voltage and good diodes so that just the filter.

Do you have an RF sig generator? If you do you can sweep the filter. It will tell you couple of things.
1. Where is Fc at (center frequency)
2. What is its attenuation

Doesnt have to be a sophisticated or accurate RF sig gen.

Can set it at around 8.0 mhz as measured by your Simpson Freq counter and set the rf output level to approx 200mv as measured by your O-scope.

Connect the output from RF sig gen to Anode of D7 and your O-scope at Anode of D8 (rig power is off) and slowly raise the frequency and see where the peak RF output voltage occurs at. Should be close to 8830.7khz. This assumes your sig gen output voltage doesnt vary greatly for small change in frequency. If it does you would need two ways to measure RF so you could ride the sig gen output to keep it constant.

Terry, with a .047 capacitor across the CW filter, I get full output in CW mode regardless of what position the IF2 connector is in.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

These are the readings taken with IF2 connector in all three positions (P-P values):
Position A: D7 cathode: 800mV CW, 800 mV FSK --- D8 cathode: 600mV CW, 400mV FSK
Position B: D7 cathode: 600mV CW, 800 mV FSK --- D8 cathode: 44mV CW, 400 mV FSK
Position C: D7 cathode: 260mV CW, 800 mv FSK --- D8 cathode: 40mV CW, 400 mV FSK
All readings were taken with my scope with the probe in the 10X position to prevent loading of the circuit.

These are the DC readings for D7 and D8 in all three positions (RMS values):
Position A: CW - D7 anode: -3.6V, cathode: 2.0V -- D8 anode: 0V, cathode: 9.0V
Position A: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode 8.5V
Position B: CW - D7 anode: 2.8V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.7V
Position B: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode: 8.5V
Position C: CW - D7 anode: 2.8V, cathode: 2.2V -- D8 anode: 9.3V, cathode: 8.6V
Position C: FSK - D7 anode: 2.7V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.6V

The only position I get output in CW mode is when the connector is in position A.

The CW filter is a TRIO YG-88C and I have re-soldered all connections on the filter.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

I meant Cathode voltages but I think you get the idea. Measure the Anode and Cathode to ensure both diodes are being switched on. Should see approx 0.65 vdc drop across D7 and D8 as they are silicon diodes.

Not likely bad but if you need to replace I offer the following:

Should you need a diode do not use a NTE 177 sub. These are 1S1587 fast switching diodes with a fast reverse recovery time of approx 2 ns so I would not use a general purpose silicon diode as NTE sub guide suggests. Can use a NTE 519, but it has a recovery time of approx 70 ns.

I think a 1N914 or 1N4148 would be better choice at 4ns..These are still pretty commonly available.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK I forgot to give you the Anode voltages of D7 and D8 but you can just subtract approx 0.65vdc for the turn on voltage.

280mv P-P is high by my measurements, but if you read close to same in FSK-T then call it good. Certainly better than be too low.

6 mv P-P at output in CW-T is definitely a problem. As I said you can jumper the filter with a .047uf cap and see if you get CW Tx.

Is this the factory YG-88C filter?

I believe it has center frequency of 8830.7 mhz.and bandwidth of 500hz at -6dB.
I have never swept one.

It would not seem likely that you would have bad solder connections if the filter is working in FSK mode. Are you 100% certain you are not using the SSB filter in FSK mode?

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

My voltages at D7 and D8 are virtually identical to yours. I had previously measured the levels at D7 and D8. I measured 280mV P-P where C14 connects to the CW filter and only 6mV P-P out of the filter. But that was before I changed the cable to position A. I will have to move the cable back to C and re-measure tomorrow. I will also pull the IF board out and resolder the CW crystal filter connections. It may be bad solder connections as you suggest.

I just made my first contact in 17 years on 7.020 with W5TZC about 30 mins ago. He gave me a 579 which is pretty good considering my antenna is only 8 feet off the ground. I also still have to address why they final isn't tuning properly on 40 meters. It tuned max power with plate knob pointer sitting on the 5 of 3.5. It dips at 14 on 20 meters.

If I can get the CW filter issue worked out I will go through a complete tuneup of the radio following the service manual procedures.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

It is easy to test CW filter switching diodes D7 and D8. I thought you already did this and reported good?

As previously noted my plug is in C all the way toward the front panel.

Conn IF-2 pins 4 and 5 have approx 12.9vdc on them in Rx and Tx for CW-R, CW-T, FSK-R, and FSK-T.

The cathode of D7 is:
CW-R and FSK-R = 2.90vdc

CW-T and FSK- T = 2.90vdc

The cathode of D8 is : (Note: When you connect voltmeter back ground noise will drop significantly).
CW-R and FSK-R = 10.0vdc
CW-T and FSK-T = 9.80vdc

The reading will be different as the diodes are biased to different current levels. You can see the difference in the supply resistors for each diode.

I have never been able to measure TX level diagram RF voltages accurately using a 1X scope probe. It will pull your ALC indication down from FSD (40 over) to approx 25 over.

You should be able to measure the 8.830mhz TIF signal level at the input and output of the CW Xtal filter. I thought we did this a long time ago?

It is normal for the filters to have an insertion loss. Should have a minimum of approx 25mv rms at D7 input and minimum of approx 19mv rms at D8 output.

Here are my RF level measurements at D7 and D8:

Test conditons: 14.175mhz, Heater on , SG switch off, CW mode, Drive control peaked, Car Pot at 2.5 (for full scale ALC deflection or 40 over)

Boonton 92E (using 10x scope probe very close to same levels)
D7 = 58mv
D8 = 25mv

You can jumper across your CW filter with a couple of mini-grabber test leads with a 0.047uf capacitor in series.

Could have good switching diodes and good filter but bad solder connections at the filter?

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I have made a discovery that will probably tell us where the actual problem is. I was googling how to replace CW filter and found this link:
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2

So I downloaded the operators manual and looked at page 34. Kenwood is perfectly clear about this. If the plug is in position A, the CW filter is bypassed.

I put the plug in position A and can tune to full power out in CW mode. If I place the plug in position B or C I get no power out when in CW mode.

Does this indicate a bad CW filter? The filter works fine in receive mode. The only thing I have noticed is that if I switch from USB to CW the signal drops 1 S-unit when peaked for max signal in both modes.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

At this point I am using my scope with 1 meg input. If is become suspicious of the reading I switch the 10X on and take the reading that way.

An immediate problem I see is I only have 10mV P-P at the drain of Q1 in FSK mode and 0 output in CW mode. The diagram says there should be 250 mV rms there. If I pull the CW filter out of the radio, how does the CW transmit work? Does the signal then go through the USB filter or do I need to install a jumper where the CW filter was?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Yes they are RMS.

I take them at around 14.175 to 14.200 mhz with the Car Level pot advanced to the point that with the Drive Control adjusted for a peak in ALC indication at panel meter full scale deflection. Then switch to CW mode and load to approx 100 watts out and turn off SG switch. Leave Car Level and Drive control alone.

Measured values will vary depending on what test instrument you are using, length of any test jumper leads used to access the test points, line voltage.

For example 8.830mhz TIF output at the IF board and input at the RF board is shown as 0.038v. This is 38.0 mv rms rf volts or 38 x 2.828 = 107 mv P-P. So if you have approx 100mv P-P TIF you are good.

Output of the TX Mixer is 1.4v rms or 4.0v P-P. This RF drive level is now 14.175 mhz.

If you plan on doing a lot of this work suggest you invest in a RF Millivolt meter. I use a Boonton 92E. I find it loads the circuits less and just easier and faster to use.

Of coures once you get to the 1.4 volts at output of the TX Mixer the old fashioned RF probe and VTVM works great. Just have to use multi-diode probe at plate of Driver tube and control grids of the Finals. I used a Heath 309C and PK-3 probes and a IM-18 VTVM for years and still have them for fall back.

Terry,

Are the transmit levels on page 42 of the service manual correct? Are those RMS values?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Thanks Terry. I have been talking to you since you have been helping. I don't know what made me put Dave on the last message (old age maybe).

I decided to start over from the beginning and go stage by stage this afternoon. This is what I did:
(All measurements taken with Send switch operated and Mode switch in CW position. Also, the measurements are the same in both CW and FSK modes.)

I suspected D1 or L1 was bad on the CAR-II board was bad but that is not the case. I have 720mV on CA2 leaving the CAR-II board in both CW and FSK send modes. I also have 720mV P-P on CA2 (IF5-13) on the IF board. I have 100mV P-P at the coax that connects to C92 on the IF board. On the other end of that coax where it connects to the top of T4 on the IF board I also have 100mV P-P. I would have thought the signal out of Q18 would have been stronger but maybe not.

I have 340mV at the junction of the cathode of D7 and C14 on the IF board. I have 280mV on the side of C14 where it feeds the CW filter. The signal going into the filter measures 8.830755 MHz. I only have 6mV P-P coming out of the crystal filter. Is the crystal filter used for transmit?

I connected the antenna to the radio and 20 meters is open. Tuning in CW signals in USB mode and switching to CW mode drops the signal by about 1 S-Unit when the signal is peaked for max signal in both modes.

Where do I go from here?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Are you talking Dave or Terry ? If someone is helping you off list I can back away as I have a pretty full plate right now.

I am not clear where you are measuring this 40mv P-P signal at?

Before I go I will mention that it is normal to not have a clean sine wave at TIF. It does have harmonic content and it is as you say due to LO mixing action. In this case it is coming from the VCO signal feeding back from the TX Mixer on RF board to the IF board.

This is easy to confirm with a TS-830 as you can easily unplug the VCO cable from the PLL board and the TIF signal will then be a nice clean 8.830mhz sine wave.

Dont worry about the complex waveform. Should still be able to get a reasonably close TIF measurement. It may not match exactly the levels on the TX Level Diagram,but you can compare it to the level you get with FSK carrier oscillator.

I dont use a O-scope to run TX Level diagrams once I get to the output of the TIF amp. I use a Boonton RF Millivolt meter and measure levels in rms and the "dirty" TIF signal presents no problem.

I have a new digital O-scope and it has a variety of digital filters. If I set it for a LP filter with a roll off frequency of 10mhz I can get a pretty clean 8.830 TIF sine wave display.

I dont know the Tek 2445 capability in this regard.

One final reminder is that good TIF signal level of approx 38mv rms or 107mv P-P is based on the premise that you accurately measured CA2 at the iF board of approx 300mv rms or

850mv P-P.

If that signal is not there then you would need to repeat the testing I asked you to do at the Carrier Osc board to confirm the 9vdc CW diode switching voltage is available at D1 and Q2 Buffer amp is being turned on.

I have been providing direction based on your reporting back that you have good CA-2 at Carrier board and good CA-2 at TP-5 on IF board.

If good Level at TP-5 then should have proper level at the wiper of VR-5 on the Balanced Mod. As we have discussed. No dc bias from CV and no Carrier at wiper of VR-5 then no output from the Bal Modulator.

I am pretty confident that you do have proper bias voltage from CCW to full CW on the Car Pot, but I am not certain yet that you have proper carrier output from the BM in CW mode.

Good luck.

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Dave,

I have VFO set to 14.175. With Car pot at 1200, in CW mode I get 40mV P-P in RX mode. When I flip the Send switch, the signal stays at 40 mV but it is no longer a sine wave. It is some kind of more or less sine wave with a lot of noise on it. With the Car pot at max, the noisy sinewave increases to 60 mV P-P in Send mode.

In FSK mode with Car at 1200 I get 250mV P-P in Send mode. With Car at Max I get 800 mV P-P in Send mode.

At Conn RF1-10 I get 140mV P-P in CW Send mode. I get 800mV P-P in FSK Send mode.

At the mixer output (Q1 and Q8 side of C8) I get 100 mV P-P in CW Send mode. I get 1V P-P in FSK Send mode. The signal at that point is not a sinewave but seems to have multiple signals. Probably some LO feedthrough on the mixer. The frequency counter agrees with the Kendwood readout as 14.1748 MHz.

Ray:

Sorry about Q10 vs Q18. My fingers work better than what is left of my brain.

The 3 conductor plug should be positioned in forward position toward the front panel.

One thing we did not talk about is whereiyou should have the Car Level Pot set to take these measurements.

The TX Level Diagram is shown in the Service Manual. These levels were taken by Kenwood by loading the rig to approx 100 watts out at 14.175mhz and then turn the SG switch off and leave Car pot alone and Drive control alone.

Since you have no RF output in CW mode I suggest you do this for remainder of the readings:

1. VFO 14.175
2. Peak the Drive Control on receiver noise or the marker signal
3. Car Level Pot 1200
4. Heater on
5. SG switch off
6. Flip to Send to take RF drive levels

So the differences in voltages may be due to where we each have our Car Level pot set at.

Suggest you measure the voltage and frequency of the TIF signal at IF-3 Pin 2 one more time and it should be approx 250mv rms or 700mv P-P @ 8830.7mhz.

If you have close to this time to move on to the RF board. I must say this is getting a little odd as you have good output ini SSB and FSK which tells us you have good TIF level and the TX Mixer on RF Board is working which means you have good VCO (LO to the mixer).

Are you 100% certain you have no CW RF output on all bands? If so, then proceed on to the RF board with Heaters On and SG off and rig peaked as noted above.

You should have close to the values noted on the TX Level Diagram. At Conn RF-1 Pin 10 the 8.830 TIF signal level is approx 38mv rms or 108 P-P.

At output of TX Mixer should have approx 1.5v rms or 4.2v P-P rf drive at MD. At MD frequency will now be 14.175mhz transmit frequency.

If you have no RF drive or very weak at MD then need to measure the VCO level and frequency at RF-1 pin 4 and on board at TP-1. Should be close to 1.0v rms level. If no VCO try on other bands.

We are making good progress. Your Tek 2445 is perfect scope for KW Hybrid work and you apparently know how to use it and can read a schematic and can locate points on these high density boards to take measurements. This really helps.

Based on your report of no RF output in CW mode I would have thought we would have found no TIF sig at output of the IF board. TIF is not band specific and often is caused by no output from the Bal Modulator, This is why I had you start by testing for bias voltage and LO signal available. Never expected that we would be at the RF board and TX Mixer based on good RF output on other modes.

Terry,

I read a little over 700mV at the drain of Q18 (actually the backside of C92 feeding the coax). I think you meant Q18 instead of Q10.

D7 and D8 are the CW switching diodes. With the mode switch in CW position, I have 2.98 volts on the anode of D7 and 2.34 volts on the cathode. I have 10.0 volts on the anode of D8 and 9.40 volts on the cathode. These voltages are there in both RX and TX, just a few 10ths of a volt lower in TX mode.

Can you confirm how the 3 pin cable ofr IF2 is supposed to plug in? It only has 3 wires but there are 5 pins on the IF board at that point. According to the chassis wiring diagram,

only the first 3 pins are used as they come from S6-1.

I don't think there is anything wrong with the CW filter and the switching diodes as the CW filter works fine in RX mode.

I have 400mV P-P on Gate 1 of Q1 instead of the 160mV when flipping Send. I also have 2400mV P-P on the drain instead of 1000mV when flipping Send.

TIF signal on Conn IF-3 is 400mV P-P and the sine wave isn't quiet as clean there as it is on the drain of Q1.

Hopefully we are making progress.

Tell me about it !
I am a CW operator normally at QRP.

So, I decided to put the Kenwood 830 'on line'.
I went through the whole SSB tuning sequence,
because that is all that was in my manual.
Then at the end they state something like
flip the switch to CW and you are ready to go.
NOT !
The SSB procedures have just canceled out your Carrier,
thus NO CW signal.

I thought I missed something, so I went back through all this several times.

Finally, I just rotated the Carrier Knob and gave myself some Carrier for the CW signal.

All went well after that.

Anyway, Kenwood 830 is a 1985 Cadillac of transceivers.
Glad to have one.
You just have to have more experience than the guy who wrote the manuals.

This is a good Group and the chatter about Kenwood topics is informative.
No magic, but good advice.

Thanks guys.

Barry,

There is really no need for you to find a "you tube video" regarding "tuning or loading up" your KW hybrid. The directions in the "operators manual" are pretty easy to follow. You can however, go look at Ken Kemski's web site: k4eaa.com there is lots of very good info on the KW hybrids, including some "simplified" instructions on "tuning up." I suggest that you practice a few "dry runs" with the controls..to get familiar with what is being told. Please use a dummy load connected to the rigs output...so you don't cause QRM. Once you get the hang of it...it's rather easy...and can be done quickly.

I do not think that "tuning up in SSB" works...as there is no input to cause any RF output, unless you inject the appropriate signal level into the microphone jack. The instructions clearly state to start out in "TUNE" this reduces voltage to the final amp tubes...so they don't get damaged by being out of tune and hit with full voltage...then go to "CW" and "fine tune" it. If you are going to use SSB...all you have to do is connect mic..select proper side band..etc
and use the MIC control to get output...while watching the "ALC reading." Again, read the manual!

Some guys will have their own "simplified" version(s)...but I suggest that, until you get familiar
with YOUR rig and how to operate it...stick to the operators manual. You, and you final tubes
will be much happier!

Very much so! The valve PAs used in these old boatanchors are quite forgiving and will put up with a bit of mistuning, but be careful all the same. If you follow the instructions in the manual it will take you ages to tune up at first, so keep one hand on the Standby switch whenever it's transmitting and be ready to drop it off at the first sign of distress.

Oh, and don't forget to give it a final little tweak on CW once your aerial is connected, because that won't be as well matched as the dummy load! I think sometimes people lose sight of this but the pi network on the output is a fairly specialised form of ATU - if your feeder and aerial were a couple of thousand ohms impedance, you could drive them directly, and squirrels wouldn't climb the wires :-)

There is no SSB loading procedure in any TS830 operating manual that I have seen and no way to load with Mode Switch in LSB or USB unless you inject audio in to the mic jack? Dont know what manual you were reading.

There is Step 4.3 Transmission that clearly describes how to load the TS830 and that is done in CW mode. At Step 9 in clearly states you are now done and fully loaded and ready for CW operation. Need to go on to the CW section to learn how to zero beat but loading is done.

If you had literally followed this Step 4.3 you would not have turned your Car Level Pot back CCW at its conclusion. Where did it direct you to do that?

Only thing they could have added is if you want to run less than 100 watts out you can reduce the Carrier Level pot position to any output power level you desire. Apparently that is not intuitive.

Some points of clarification:

1. Manual says to check resting plate current and set to 60ma. No need to do that every time you load the rig. OK to do, but not required. Once set should not change for a long time. If rig is new to you then should clean the bias voltage adjust pot on rear panel with deoxit and blow out with canned air and adjust for 60ma. You are setting the zero signal operating point (Class AB1).

2. Almost everyone has a question about Step 5 adjusting the Drive control to peak the ALC indication. What ALC peak? Do they mean the printed black rectangular box or the full scale of the panel meter? IT DOES NO MATTER. You are not reading any of the meter scales. You are NOT setting grid current levels. You are adjusting the Transmit Mixer and Transmit Drive tuned circuits for resonance so you will have maximum RF drive (voltage swing) at the control grids of the 6146 finals. Videos will go to great length to show that you must keep ALC indication in the center of the black printed range or at the far right edge of it and to go back and check it after loading and if not to adjust it. All of this is bogus and shows no understanding of what this step is. Some of this comes from long time hams. Just advance the Car Level pot to get a decent indicated level that you can peak. If the level of carrier pegs the meter simply back the Car Pot down a little.

3. After adjusting the Plate Tune cap for a dip in Plate current (Ip) in Tune mode all the KW hybrid manuals have you flip meter to RF Relative Power position to load to maximum relative power output and as a last step go back to Ip meter position to make sure not exceeding maximum plate dissipation. 200ma for the 520/820 rigs and 265ma for the 530/830 rigs. Most 530/830 owners do not load much above 225ma in effort to extend tube life.

No where does KW recommend you load the radio using the plate current Dip and Load method. Old timers do this as they learned it from Class C grid leak bias CW transmitter days. It was only game in town as there were no external wattmeters and they had to watch grid current so they didnt exceed 6146 final tube control grid dissipation and damage the tubes. None of that applies to a KW Hybrid. It is a Class AB1 linear amp. For this reason KW gave

you the RF Relative Power meter position to load the radio. In Class AB1 loading to max rf output without exceeding max plate dissipation will result in the max load (best efficiency) occurring slightly to inductive side of true resonance. Hard to see the actual minimum dip in Class AB1 tetrode amps.

4. For all new folks I suggest that since you need a SWR bridge to trim your dipoles do yourself a favor and buy a wattmeter like a Drake W4 or Heath HM-102 and you now have your SWR bridge and a KW hybrid loading aid and test meter. Instead of using the RF meter position leave rig meter in IP and load for maximum RF output power on the external wattmeter (this will be approx 100 watts out or a little less) without exceeding approx 200 to 225 ma. 225ma is a level that Ken K4EAA recommends to ensure long tube life. It is not a hard number.

Using the Wattmeter gives a real power number to look at and simplifies loading and gives instant indication of problems with the rig or your antenna system. These are problems that you as a new person would not likely recognize or understand looking at the Ip meter indication.

Loading one of these radios can be accomplished literally in seconds.

If you pre-set the controls can be done even in CW mode to get that initial plate current dip. Not recommended until you gain some experience.

I have seen no You Tube videos that I would recommend. Most are flawed especially when it comes to peaking the ALC indication and that includes those posted by Extra class holders. Lots of good intentions and little technical understanding of what is happening on the ends of the control knob shafts.

Until you gain some knowledge and experience if you can read, read with comprehension, and observe literal procedure compliance, then the loading procedure steps in all the manuals works just fine.

Topic: 45554 Message: 45554

I have never used my TS 830 on 12 meters. Yesterday it seemed to load up fine. The power would fall way back and I would not get any alc. I could peak the watt meter in tune to a few watts. I could switch to another band, come back and it would work correctly for a few seconds. Only happens on 12 meters.

The survival guide says it is the back to sections of the band switch. Use conductive paint between the stationary lub and the copper foil on the board. Has anyone done this fix with success? What paint do I need to use. I would rather use something other than paint, is there another method?

Thanks

Ray

Apparently I am wrong about in situ sweeping of the CW filter by injecting inside Anode of D7 and measuring inside Anode of D8 and using no series source resistor at the input and no shunt load resistor at the output.

As I previously mentioned using these resistors is standard practice for testing crystal lattice filters on the bench. If you know the values of the internal input and output capacitors (not likely unless you are homebrewing the filters) there are formulas for calculating the resistance values absent knowing the factory impedance values. I have had good success using two resistor divider at input and output or using a pot to ground on each end and connecting the sig gen and rf measuring device to the wipers of the pots. Can then adjust the pots to get the optimum signal levels.

I had hoped this short cut method would show if the Fc had radically shifted and/or if there was an inordinate amount of signal attenuation.

I performed your test method on my TS820 CW filter early this am and the peak RF voltage occurred at 8830.52 and not 8830.70. By those results we would say my filter is bad and I know it is not as I get full CW output with it and my CA-2 carrier frequency is spot on 8830.7.

A couple of other in situ methods come to mind:

1. Rig powered off
2. Apply 12vdc from a dc bench supply or couple of lantern batteries to Molex Conn IF-2 Pins 4 and 5. This will turn on D7 and D8 filter switching diodes.
3. Inject test Rf signal at Cathode of D7 and measure the RF output at cathode of D8.

4. This method inserts the source and load resistance that the filter sees in operation.

OR

1. Rig powered on
2. Disable CA-2 8830.7 input to IF board
3. Inject test RF signal at TP-5
4. Measure RF output at cathode of D8.

I have a pretty full plate today so will think about this and perhaps after dinner tonite can try one or both of these above methods.

Ray

Much better got it all this time.

Yes the diode barrier voltages will vary as the dc supply and line voltage will also vary. As long at the diodes are the original silicon diodes then 0.6vdc to 0.7vdc is typical. You are looking for gross differences between what I read. I looked at your readings and I agree the diodes are fine and the switching voltage supply to them is there.

Yes for most accurate sweep should terminate filter input and output in its characteristic impedance, but for this test what you have should be OK as we are only interested in relative rf voltages. I dont know what the input/output impedance of this filter is. Most of the KW filters have impedances that range from 300 ohms to 2k ohms that I have seen. You could experiment and repeat test with resistor divider on each end.

When I sweep a KW filter out of the rig on the bench I look at service manual for the input/output impedance. I then make a 2 resistor divider at each side of the filter. For example if the filter Z is 600 ohms I will place a 600 ohm resistor in series with the filter input and a 50 ohm resistor in shunt to ground. I connect the sig gen to the free end of the 600 ohm series resistor. Do same at output and connect the O-scope or RF millivolt meter to the free end of the 600 ohm resistor.

You can see that if your CW TX carrier frequency is 8830.7 as it should be then it will be outside the -6dB bandpass of the filter if the measured FC is 8830.3.

I will try to get time tomorrow and sweep my filter in place using same method you employed for comparison.

What you know for sure is :
1. D7/D8 are being biased on in CW mode.
2. With .047 cap bridging the filter you get full RF output in CW mode
3. With cap removed no RF output

Sure looks like filter is the culprit.

You are doing some good work here. Absent test gear, knowing how to use it, ability to read a schematic, and some familiarization with the board layouts this is a challenging task for any hybrid owner.

I will get back with my sweep results.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

Let me try again. The unreadable post has been happening a lot since Yahoo went to this new format last month.

With the .047 cap on the anodes of D7 and D8 I am able to obtain full output in CW mode. Also, both diodes are forward biased in CW Send mode as I see approximately .6 volts drop across them in Pos C. The voltages are about .1 volt lower than what you are showing.

Do you know the impedance of the crystal filters in the TS-820? This is the signal source I have to use to test with:
http://www.oocities.org/hagtronics/source/index.html
It has a 50 ohm output. I also have a HP 3314A I could use but it is also 50 ohms out.

With the signal source set to -1 dB out and in and out connections at the anodes of D7 and D8, I get these are the readings I get:
8.8300 - -46.9 dB
8.8301 - -33.3 dB
8.8302 - -19.5 dB
8.8303 - -14.4 dB
8.8304 - -17.5 dB
8.8305 - -26.4 dB
8.8306 - -28-5 dB
8.8307 - -42.5 dB
8.8308 - -49.5 dB
8.8309 - -49.7 dB
8.8310 - -50.0 dB

The filter FC appears to be at 8.8303. My scope with 1 meg load agrees with this as I see the peak on it at the same frequency. I don't know how much the 50 ohm generator and power meter loads are affecting the filter.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray that is because you have the test cap on the Cathode sides of D7 and D8. Move the cap to the Anode sides of each and the plug to Pos C. Now you are checking the diodes as well.

This test proves that you have sufficient RF carrier level from the BM available at the Cathode of D7 to produce full output in CW.

Problem is if jumpering the filter works then which is bad? The CW filter or one or both diodes or the bias supply to the diodes?

I would focus all my efforts with the plug in Pos C to simplify reading taking.

In Pos C you need to ensure that each diode is forward biased.

D7 Cathode = 2.85vdc
D7 Anode = 2.25vdc

D8 Cathode = 9.8vdc
D8 Anode = 9.2vdc

Pretty sure you have already done this and confirmed you have diode supply voltage and good diodes so that just the filter.

Do you have an RF sig generator? If you do you can sweep the filter. It will tell you couple of things.
1. Where is Fc at (center frequency)
2. What is its attenuation

Doesnt have to be a sophisticated or accurate RF sig gen.

Can set it at around 8.0 mhz as measured by your Simpson Freq counter and set the rf output level to approx 200mv as measured by your O-scope.

Connect the output from RF sig gen to Anode of D7 and your O-scope at Anode of D8 (rig power is off) and slowly raise the frequency and see where the peak RF output voltage occurs at. Should be close to 8830.7khz. This assumes your sig gen output voltage doesnt vary greatly for small change in frequency. If it does you would need two ways to measure RF so you could ride the sig gen output to keep it constant.

Terry K9TW

Terry, with a .047 capacitor across the CW filter, I get full output in CW mode regardless of what position the IF2 connector is in.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

These are the readings taken with IF2 connector in all three positions (P-P values):
Position A: D7 cathode: 800mV CW, 800 mV FSK --- D8 cathode: 600mV CW, 400mV FSK
Position B: D7 cathode: 600mV CW, 800 mV FSK --- D8 cathode: 44mV CW, 400 mV FSK
Position C: D7 cathode: 260mV CW, 800 mv FSK --- D8 cathode: 40mV CW, 400 mV FSK
All readings were taken with my scope with the probe in the 10X position to prevent loading of the circuit.

These are the DC readings for D7 and D8 in all three positions (RMS values):
Position A: CW - D7 anode: -3.6V, cathode: 2.0V -- D8 anode: 0V, cathode: 9.0V
Position A: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode 8.5V
Position B: CW - D7 anode: 2.8V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.7V
Position B: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode: 8.5V
Position C: CW - D7 anode: 2.8V, cathode: 2.2V -- D8 anode: 9.3V, cathode: 8.6V
Position C: FSK - D7 anode: 2.7V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.6V

The only position I get output in CW mode is when the connector is in position A.

The CW filter is a TRIO YG-88C and I have re-soldered all connections on the filter.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

I meant Cathode voltages but I think you get the idea. Measure the Anode and Cathode to ensure both diodes are being switched on. Should see approx 0.65 vdc drop across D7 and D8 as they are silicon diodes.

Not likely bad but if you need to replace I offer the following:

Should you need a diode do not use a NTE 177 sub. These are 1S1587 fast switching diodes with a fast reverse recovery time of approx 2 ns so I would not use a general purpose silicon diode as NTE sub guide suggests. Can use a NTE 519, but it has a recovery time of approx 70 ns.

I think a 1N914 or 1N4148 would be better choice at 4ns..These are still pretty commonly available.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK I forgot to give you the Anode voltages of D7 and D8 but you can just subtract approx 0.65vdc for the turn on voltage.

280mv P-P is high by my measurements, but if you read close to same in FSK-T then call it good. Certainly better than be too low.

6 mv P-P at output in CW-T is definitely a problem. As I said you can jumper the filter with a .047uf cap and see if you get CW Tx.

Is this the factory YG-88C filter?

I believe it has center frequency of 8830.7 mhz.and bandwidth of 500hz at -6dB.
I have never swept one.

It would not seem likely that you would have bad solder connections if the filter is working in FSK mode. Are you 100% certain you are not using the SSB filter in FSK mode?

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

My voltages at D7 and D8 are virtually identical to yours. I had previously measured the levels at D7 and D8. I measured 280mV P-P where C14 connects to the CW filter and only 6mV P-P out of the filter. But that was before I changed the cable to position A. I will have to move the cable back to C and re-measure tomorrow. I will also pull the IF board out and resolder the CW crystal filter connections. It may be bad solder connections as you suggest.

I just made my first contact in 17 years on 7.020 with W5TZC about 30 mins ago. He gave me a 579 which is pretty good considering my antenna is only 8 feet off the ground. I also still have to address why they final isn't tuning properly on 40 meters. It tuned max power with plate knob pointer sitting on the 5 of 3.5. It dips at 14 on 20 meters.

If I can get the CW filter issue worked out I will go through a complete tuneup of the radio following the service manual procedures.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

It is easy to test CW filter switching diodes D7 and D8. I thought you already did this and reported good?

As previously noted my plug is in C all the way toward the front panel.

Conn IF-2 pins 4 and 5 have approx 12.9vdc on them in Rx and Tx for CW-R, CW-T, FSK-R, and FSK-T.

The cathode of D7 is:
CW-R and FSK-R = 2.90vdc
CW-T and FSK- T = 2.90vdc

The cathode of D8 is : (Note: When you connect voltmeter back ground noise will drop significantly).
CW-R and FSK-R = 10.0vdc
CW-T and FSK-T = 9.80vdc

The reading will be different as the diodes are biased to different current levels. You can see the difference in the supply resistors for each diode.

I have never been able to measure TX level diagram RF voltages accurately using a 1X scope probe. It will pull your ALC indication down from FSD (40 over) to approx 25 over.

You should be able to measure the 8.830mhz TIF signal level at the input and output of the CW Xtal filter. I thought we did this a long time ago?

It is normal for the filters to have an insertion loss. Should have a minimum of approx 25mv rms at D7 input and minimum of approx 19mv rms at D8 output.

Here are my RF level measurements at D7 and D8:

Test conditons: 14.175mhz, Heater on , SG switch off, CW mode, Drive control peaked, Car Pot at 2.5 (for full scale ALC deflection or 40 over)

Boonton 92E (using 10x scope probe very close to same levels)
D7 = 58mv
D8 = 25mv

You can jumper across your CW filter with a couple of mini-grabber test leads with a 0.047uf capacitor in series.

Could have good switching diodes and good filter but bad solder connections at the filter?

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I have made a discovery that will probably tell us where the actual problem is. I was googling how to replace CW filter and found this link:
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2

So I downloaded the operators manual and looked at page 34. Kenwood is perfectly clear about this. If the plug is in position A, the CW filter is bypassed.

I put the plug in position A and can tune to full power out in CW mode. If I place the plug in position B or C I get no power out when in CW mode.

Does this indicate a bad CW filter? The filter works fine in receive mode. The only thing I have noticed is that if I switch from USB to CW the signal drops 1 S-unit when peaked for max signal in both modes.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

At this point I am using my scope with 1 meg input. If is become suspicious of the reading I switch the 10X on and take the reading that way.

An immediate problem I see is I only have 10mV P-P at the drain of Q1 in FSK mode and 0 output in CW mode. The diagram says there should be 250 mV rms there. If I pull the CW filter out of the radio, how does the CW transmit work? Does the signal then go through the

USB filter or do I need to install a jumper where the CW filter was?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Yes they are RMS.

I take them at around 14.175 to 14.200 mhz with the Car Level pot advanced to the point that with the Drive Control adjusted for a peak in ALC indication at panel meter full scale deflection. Then switch to CW mode and load to approx 100 watts out and turn off SG switch. Leave Car Level and Drive control alone.

Measured values will vary depending on what test instrument you are using, length of any test jumper leads used to access the test points, line voltage.

For example 8.830mhz TIF output at the IF board and input at the RF board is shown as 0.038v. This is 38.0 mv rms rf volts or 38 x 2.828 = 107 mv P-P. So if you have approx 100mv P-P TIF you are good.

Output of the TX Mixer is 1.4v rms or 4.0v P-P. This RF drive level is now 14.175 mhz.

If you plan on doing a lot of this work suggest you invest in a RF Millivolt meter. I use a Boonton 92E. I find it loads the circuits less and just easier and faster to use.

Of coures once you get to the 1.4 volts at output of the TX Mixer the old fashioned RF probe and VTVM works great. Just have to use multi-diode probe at plate of Driver tube and control grids of the Finals. I used a Heath 309C and PK-3 probes and a IM-18 VTVM for years and still have them for fall back.

Terry,

Are the transmit levels on page 42 of the service manual correct? Are those RMS values?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Thanks Terry. I have been talking to you since you have been helping. I don't know what made me put Dave on the last message (old age maybe).

I decided to start over from the beginning and go stage by stage this afternoon. This is what I did:
(All measurements taken with Send switch operated and Mode switch in CW position. Also, the measurements are the same in both CW and FSK modes.)

I suspected D1 or L1 was bad on the CAR-II board was bad but that is not the case. I have 720mV on CA2 leaving the CAR-II board in both CW and FSK send modes. I also have 720mV P-P on CA2 (IF5-13) on the IF board. I have 100mV P-P at the coax that connects to C92 on the IF board. On the other end of that coax where it connects to the top of T4 on the IF board I also have 100mV P-P. I would have thought the signal out of Q18 would have been stronger

but maybe not.

I have 340mV at the junction of the cathode of D7 and C14 on the IF board. I have 280mV on the side of C14 where it feeds the CW filter. The signal going into the filter measures 8.830755 MHz. I only have 6mV P-P coming out of the crystal filter. Is the crystal filter used for transmit?

I connected the antenna to the radio and 20 meters is open. Tuning in CW signals in USB mode and switching to CW mode drops the signal by about 1 S-Unit when the signal is peaked for max signal in both modes.

Where do I go from here?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Are you talking Dave or Terry ? If someone is helping you off list I can back away as I have a pretty full plate right now.

I am not clear where you are measuring this 40mv P-P signal at?

Before I go I will mention that it is normal to not have a clean sine wave at TIF. It does have harmonic content and it is as you say due to LO mixing action. In this case it is coming from the VCO signal feeding back from the TX Mixer on RF board to the IF board.

This is easy to confirm with a TS-830 as you can easily unplug the VCO cable from the PLL board and the TIF signal will then be a nice clean 8.830mhz sine wave.

Dont worry about the complex waveform. Should still be able to get a reasonably close TIF measurement. It may not match exactly the levels on the TX Level Diagram,but you can compare it to the level you get with FSK carrier oscillator.

I dont use a O-scope to run TX Level diagrams once I get to the output of the TIF amp. I use a Boonton RF Millivolt meter and measure levels in rms and the "dirty" TIF signal presents no problem.

I have a new digital O-scope and it has a variety of digital filters. If I set it for a LP filter with a roll off frequency of 10mhz I can get a pretty clean 8.830 TIF sine wave display.

I dont know the Tek 2445 capability in this regard.

One final reminder is that good TIF signal level of approx 38mv rms or 107mv P-P is based on the premise that you accurately measured CA2 at the iF board of approx 300mv rms or 850mv P-P.

If that signal is not there then you would need to repeat the testing I asked you to do at the Carrier Osc board to confirm the 9vdc CW diode switching voltage is available at D1 and Q2 Buffer amp is being turned on.

I have been providing direction based on your reporting back that you have good CA-2 at Carrier board and good CA-2 at TP-5 on IF board.

If good Level at TP-5 then should have proper level at the wiper of VR-5 on the Balanced Mod. As we have discussed. No dc bias from CV and no Carrier at wiper of VR-5 then no output from the Bal Modulator.

I am pretty confident that you do have proper bias voltage from CCW to full CW on the Car Pot, but I am not certain yet that you have proper carrier output from the BM in CW mode.

Good luck.

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Dave,

I have VFO set to 14.175. With Car pot at 1200, in CW mode I get 40mV P-P in RX mode. When I flip the Send switch, the signal stays at 40 mV but it is no longer a sine wave. It is some kind of more or less sine wave with a lot of noise on it. With the Car pot at max, the noisy sinewave increases to 60 mV P-P in Send mode.

In FSK mode with Car at 1200 I get 250mV P-P in Send mode. With Car at Max I get 800 mV P-P in Send mode.

At Conn RF1-10 I get 140mV P-P in CW Send mode. I get 800mV P-P in FSK Send mode.

At the mixer output (Q1 and Q8 side of C8) I get 100 mV P-P in CW Send mode. I get 1V P-P in FSK Send mode. The signal at that point is not a sinewave but seems to have multiple signals. Probably some LO feedthrough on the mixer. The frequency counter agrees with the Kendwood readout as 14.1748 MHz.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Sorry about Q10 vs Q18. My fingers work better than what is left of my brain.

The 3 conductor plug should be positioned in forward position toward the front panel.

One thing we did not talk about is whereiyou should have the Car Level Pot set to take these measurements.

The TX Level Diagram is shown in the Service Manual. These levels were taken by Kenwood by loading the rig to approx 100 watts out at 14.175mhz and then turn the SG switch off and leave Car pot alone and Drive control alone.

Since you have no RF output in CW mode I suggest you do this for remainder of the readings:

1. VFO 14.175
2. Peak the Drive Control on receiver noise or the marker signal
3. Car Level Pot 1200
4. Heater on
5. SG switch off

They are talking about the silver conductive pen repair method described on Ken K4EAA web site.

I dont silver anymore. I solder small wires from the window of the hair pin loop to the PC traces being careful not to use too much heat to hurt the spring temper.

Either method cannot be done in place. It is a major job. Look at the pictures on Kens website.

Dick W0NTA has lots of experience with the jumper method. Might write him and ask for any tips. I very good de-soldering tool really helps and much less chance of lifting a foil. Hakko 808 gun is about best I have ever used, but like all tools comes at a price. It can be done with solder wick. .

I would be 100 percent certain if it is bad bandswitch contact before pulling the RF board.

Did you try applying some Deoxit? Use artist brush, Q-tip, tooth pick and apply sparingly. Exercise and blow out with canned air.

Terry K9TW

That is a very good question - why is it bent in the first place?? I THINK it's S5-2 the rotary switch 28/10 meter at the rear of the band shaft in the compartment with the antenna relay. I had no clue what the switch even did from the online pdf wiring diagrams. It wasn't until I looked at the original diagram with the orange print in the manual. I am confused (related to my lack of comfort/knowledge on wiring diagrams) are the three dashed lines connected on that switch telling me that VC2, C20, and (unmarked on my pdf) telling me that those three are in parallel whenever the switch is in one of two positions?
On the plus side, I have learned how to change the fuse and now have 4 correct spares in stock!

Brian,

Neutralizing your finals should be done when they are replaced, as you noted. Unless you do a major alignment, or suspect trouble with them(no need to go into that here)...no reason to mess with them.

 The "fingers" are made of several metals...and designed to be "springy." First question is:
"why is it bent out in the first place?" Also, WHICH band switch wafer? You can use a tuning tool or, other suitable item, to GENTLY apply pressure to the contact(s)

>First thank you to everyone who has posted both questions and answers, being a new operator I've already learned a lot from previous messages and files. I'm still learning and very green (i'm not the quickest at dipping and peaking yet or even finding all the knobs) but my question is with a 10 meter dipole I have, I read a higher SWR on the 28.5 band switch settings, and much lower SWR's on the 28 band and 29.1 band. If I understand everything I've learned so far, this is opposite of what I would expect. I.e., I should be reading one low SWR somewhere, and increasingly higher SWR's. Since to me it seems inverted of what is should be, what should I be focusing on? Also possibly related if i'm not consistently doing it, is the need to dip and peak when changing "bands" related to the band switch on the radio or just the general ham band, meaning that you only dip and peak once for 10 meter instead of each of the three 10 meter band switch settings.

>>
>>

>>
>>
>>First thank you to everyone who has posted both questions and answers, being a new operator I've already learned a lot from previous messages and files. I'm still learning and very green (i'm not the quickest at dipping and peaking yet or even finding all the knobs) but my question is with a 10 meter dipole I have, I read a higher SWR on the 28.5 band switch settings, and much lower SWR's on the 28 band and 29.1 band. If I understand everything I've learned so far, this is opposite of what I would expect. I.e., I should be reading one low SWR somewhere, and increasingly higher SWR's. Since to me it seems inverted of what is should be, what should I be focusing on? Also possibly related if i'm not consistently doing it, is the need to dip and peak when changing "bands" related to the band switch on the radio or just the general ham band, meaning that you only dip and peak once for 10 meter instead of each of the three 10 meter band switch settings.

45560. Re: [TS-520_820_530_830] RE: No ALC on 12 meters....

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-29 16:44:17 UTC
From: Craig Roberts
Topic: 45554 Message: 45560

The silver conductive paint method of band switch repair runs no risk of destroying the temper of the delicate switch contacts with excessive heat but is allegedly less effective and permanent (at least according to one source). Nevertheless, it seems worth trying if simple switch contact cleaning does not work. The conductive paint in question is readily available at Radio Shack.

I have a TS-530S that, after many years of apparent disuse (not abuse) arrived DOA at my shack. After a thorough band switch cleaning, the last two switch wafers (nearest the finals) were removed, their contacts bridged to the board, and soldered. The radio has been trouble free since, though the surgery may have been purely elective and not really necessary.

Y'see, on the other hand, I have a TS-830S which was almost equally unresponsive when I bought it. In that case, an afternoon with DeoxIT, an artist's brush and an air compressor (at about 50 psi) brought it back to glitch-free life. Of course, I am told by some dark thinkers that the contact cleaning (not painting or soldering) will work only temporarily. We shall see.

I have hopes that, with regular use on all bands, the TS-830S will remain in fine fettle. I have reason for optimism. The previous owner told me that he had used the radio just once a year (Field Day) on one band only (40 meters) and had not operated on any other band for a couple of decades. Sure enough, the radio worked fine on 40 meters but the transmitter was dead on all others.

As has been pointed out numerous times on this forum, dirty contacts on switches and headers are the most common cause of Kenwood hybrid problems. Yaesus of a similar vintage suffer the same fate -- and you haven;t lived until you've had to clean every single metal-to-metal junction on a Drake TR-7 (a wonderful and woefully underrated radio, by the way).

Have fun!

73,

Craig
W3CRR

Terry,

I won't be able to get to it this evening but tomorrow I am going to pull the CW filter out of the radio. I have looked at quite a few sites on the internet and it looks like the filter may be designed for 600 ohm in and out. I will setup my jig with those values and sweep it to see what the results are.

Let me know if you have any other thoughts. I see a couple of the filters on Ebay for around $90 so that may be the route I end up taking depending on what the sweep shows tomorrow. If it turns out the filter isn't bad I could always re-sale the one I bought.

Ray

Apparently I am wrong about in situ sweeping of the CW filter by injecting inside Anode of D7 and measuring inside Anode of D8 and using no series source resistor at the input and no shunt load resistor at the output.

As I previously mentioned using these resistors is standard practice for testing crystal lattice filters on the bench. If you know the values of the internal input and output capacitors (not likely unless you are homebrewing the filters) there are formulas for calculating the resistance values absent knowing the factory impedance values. I have had good success using two resistor divider at input and output or using a pot to ground on each end and connecting the sig gen and rf measuring device to the wipers of the pots. Can then adjust the pots to get the optimum signal levels.

I had hoped this short cut method would show if the Fc had radically shifted and/or if there was an inordinate amount of signal attenuation.

I performed your test method on my TS820 CW filter early this am and the peak RF voltage occurred at 8830.52 and not 8830.70. By those results we would say my filter is bad and I know it is not as I get full CW output with it and my CA-2 carrier frequency is spot on 8830.7.

A couple of other in situ methods come to mind:

1. Rig powered off
2. Apply 12vdc from a dc bench supply or couple of lantern batteries to Molex Conn IF-2 Pins 4 and 5. This will turn on D7 and D8 filter switching diodes.
3. Inject test Rf signal at Cathode of D7 and measure the RF output at cathode of D8.

4. This method inserts the source and load resistance that the filter sees in operation.

OR

1. Rig powered on
2. Disable CA-2 8830.7 input to IF board
3. Inject test RF signal at TP-5
4. Measure RF output at cathode of D8.

I have a pretty full plate today so will think about this and perhaps after dinner tonite can try one or both of these above methods.

Much better got it all this time.

Yes the diode barrier voltages will vary as the dc supply and line voltage will also vary. As long at the diodes are the original silicon diodes then 0.6vdc to 0.7vdc is typical. You are looking for gross differences between what I read. I looked at your readings and I agree the diodes are fine and the switching voltage supply to them is there.

Yes for most accurate sweep should terminate filter input and output in its characteristic impedance, but for this test what you have should be OK as we are only interested in relative rf voltages. I dont know what the input/output impedance of this filter is. Most of the KW filters have impedances that range from 300 ohms to 2k ohms that I have seen. You could experiment and repeat test with resistor divider on each end.

When I sweep a KW filter out of the rig on the bench I look at service manual for the input/output impedance. I then make a 2 resistor divider at each side of the filter. For example if the filter Z is 600 ohms I will place a 600 ohm resistor in series with the filter input and a 50 ohm resistor in shunt to ground. I connect the sig gen to the free end of the 600 ohm series resistor. Do same at output and connect the O-scope or RF millivolt meter to the free end of the 600 ohm resistor.

You can see that if your CW TX carrier frequency is 8830.7 as it should be then it will be outside the -6dB bandpass of the filter if the measured FC is 8830.3.

I will try to get time tomorrow and sweep my filter in place using same method you employed for comparison.

What you know for sure is :
1. D7/D8 are being biased on in CW mode.
2. With .047 cap bridging the filter you get full RF output in CW mode
3. With cap removed no RF output

Sure looks like filter is the culprit.

You are doing some good work here. Absent test gear, knowing how to use it, ability to read a schematic, and some familiarization with the board layouts this is a challenging task for any hybrid owner.

I will get back with my sweep results.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

Let me try again. The unreadable post has been happening a lot since Yahoo went to this new format last month.

With the .047 cap on the anodes of D7 and D8 I am able to obtain full output in CW mode. Also, both diodes are forward biased in CW Send mode as I see approximately .6 volts drop across them in Pos C. The voltages are about .1 volt lower than what you are showing.

Do you know the impedance of the crystal filters in the TS-820? This is the signal source I have to use to test with:
http://www.oocities.org/hagtronics/source/index.html
It has a 50 ohm output. I also have a HP 3314A I could use but it is also 50 ohms out.

With the signal source set to -1 dB out and in and out connections at the anodes of D7 and D8, I get these are the readings I get:
8.8300 - -46.9 dB
8.8301 - -33.3 dB
8.8302 - -19.5 dB
8.8303 - -14.4 dB
8.8304 - -17.5 dB
8.8305 - -26.4 dB
8.8306 - -28-5 dB
8.8307 - -42.5 dB
8.8308 - -49.5 dB
8.8309 - -49.7 dB
8.8310 - -50.0 dB

The filter FC appears to be at 8.8303. My scope with 1 meg load agrees with this as I see the peak on it at the same frequency. I don't know how much the 50 ohm generator and power meter loads are affecting the filter.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray that is because you have the test cap on the Cathode sides of D7 and D8. Move the cap to the Anode sides of each and the plug to Pos C. Now you are checking the diodes as well.

This test proves that you have sufficient RF carrier level from the BM available at the Cathode of D7 to produce full output in CW.

Problem is if jumpering the filter works then which is bad? The CW filter or one or both diodes or the bias supply to the diodes?

I would focus all my efforts with the plug in Pos C to simplify reading taking.

In Pos C you need to ensure that each diode is forward biased.

D7 Cathode = 2.85vdc
D7 Anode = 2.25vdc

D8 Cathode = 9.8vdc
D8 Anode = 9.2vdc

Pretty sure you have already done this and confirmed you have diode supply voltage and good diodes so that just the filter.

Do you have an RF sig generator? If you do you can sweep the filter. It will tell you couple of things.
1. Where is Fc at (center frequency)
2. What is its attenuation

Doesnt have to be a sophisticated or accurate RF sig gen.

Can set it at around 8.0 mhz as measured by your Simpson Freq counter and set the rf output level to approx 200mv as measured by your O-scope.

Connect the output from RF sig gen to Anode of D7 and your O-scope at Anode of D8 (rig power is off) and slowly raise the frequency and see where the peak RF output voltage occurs at. Should be close to 8830.7khz. This assumes your sig gen output voltage doesnt vary greatly for small change in frequency. If it does you would need two ways to measure RF so you could ride the sig gen output to keep it constant.

Terry, with a .047 capacitor across the CW filter, I get full output in CW mode regardless of what position the IF2 connector is in.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

These are the readings taken with IF2 connector in all three positions (P-P values):
Position A: D7 cathode: 800mV CW, 800 mV FSK --- D8 cathode: 600mV CW, 400mV FSK
Position B: D7 cathode: 600mV CW, 800 mV FSK --- D8 cathode: 44mV CW, 400 mV FSK
Position C: D7 cathode: 260mV CW, 800 mv FSK --- D8 cathode: 40mV CW, 400 mV FSK
All readings were taken with my scope with the probe in the 10X position to prevent loading of the circuit.

These are the DC readings for D7 and D8 in all three positions (RMS values):
Position A: CW - D7 anode: -3.6V, cathode: 2.0V -- D8 anode: 0V, cathode: 9.0V
Position A: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode 8.5V
Position B: CW - D7 anode: 2.8V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.7V
Position B: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode: 8.5V
Position C: CW - D7 anode: 2.8V, cathode: 2.2V -- D8 anode: 9.3V, cathode: 8.6V
Position C: FSK - D7 anode: 2.7V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.6V

The only position I get output in CW mode is when the connector is in position A.

The CW filter is a TRIO YG-88C and I have re-soldered all connections on the filter.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

I meant Cathode voltages but I think you get the idea. Measure the Anode and Cathode to ensure both diodes are being switched on. Should see approx 0.65 vdc drop across D7 and D8 as they are silicon diodes.

Not likely bad but if you need to replace I offer the following:

Should you need a diode do not use a NTE 177 sub. These are 1S1587 fast switching diodes with a fast reverse recovery time of approx 2 ns so I would not use a general purpose

silicon diode as NTE sub guide suggests. Can use a NTE 519, but it has a recovery time of approx 70 ns.

I think a 1N914 or 1N4148 would be better choice at 4ns..These are still pretty commonly available.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK I forgot to give you the Anode voltages of D7 and D8 but you can just subtract approx 0.65vdc for the turn on voltage.

280mv P-P is high by my measurements, but if you read close to same in FSK-T then call it good. Certainly better than be too low.

6 mv P-P at output in CW-T is definitely a problem. As I said you can jumper the filter with a .047uf cap and see if you get CW Tx.

Is this the factory YG-88C filter?

I believe it has center frequency of 8830.7 mhz.and bandwidth of 500hz at -6dB.
I have never swept one.

It would not seem likely that you would have bad solder connections if the filter is working in FSK mode. Are you 100% certain you are not using the SSB filter in FSK mode?

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

My voltages at D7 and D8 are virtually identical to yours. I had previously measured the levels at D7 and D8. I measured 280mV P-P where C14 connects to the CW filter and only 6mV P-P out of the filter. But that was before I changed the cable to position A. I will have to move the cable back to C and re-measure tomorrow. I will also pull the IF board out and resolder the CW crystal filter connections. It may be bad solder connections as you suggest.

I just made my first contact in 17 years on 7.020 with W5TZC about 30 mins ago. He gave me a 579 which is pretty good considering my antenna is only 8 feet off the ground. I also still have to address why they final isn't tuning properly on 40 meters. It tuned max power with plate knob pointer sitting on the 5 of 3.5. It dips at 14 on 20 meters.

If I can get the CW filter issue worked out I will go through a complete tuneup of the radio following the service manual procedures.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

It is easy to test CW filter switching diodes D7 and D8. I thought you already did this and reported good?

As previously noted my plug is in C all the way toward the front panel.

Conn IF-2 pins 4 and 5 have approx 12.9vdc on them in Rx and Tx for CW-R, CW-T, FSK-R, and FSK-T.

The cathode of D7 is:
CW-R and FSK-R = 2.90vdc
CW-T and FSK- T = 2.90vdc

The cathode of D8 is : (Note: When you connect voltmeter back ground noise will drop significantly).
CW-R and FSK-R = 10.0vdc
CW-T and FSK-T = 9.80vdc

The reading will be different as the diodes are biased to different current levels. You can see the difference in the supply resistors for each diode.

I have never been able to measure TX level diagram RF voltages accurately using a 1X scope probe. It will pull your ALC indication down from FSD (40 over) to approx 25 over.

You should be able to measure the 8.830mhz TIF signal level at the input and output of the CW Xtal filter. I thought we did this a long time ago?

It is normal for the filters to have an insertion loss. Should have a minimum of approx 25mv rms at D7 input and minimum of approx 19mv rms at D8 output.

Here are my RF level measurements at D7 and D8:

Test conditons: 14.175mhz, Heater on , SG switch off, CW mode, Drive control peaked, Car Pot at 2.5 (for full scale ALC deflection or 40 over)

Boonton 92E (using 10x scope probe very close to same levels)
D7 = 58mv
D8 = 25mv

You can jumper across your CW filter with a couple of mini-grabber test leads with a 0.047uf capacitor in series.

Could have good switching diodes and good filter but bad solder connections at the filter?

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I have made a discovery that will probably tell us where the actual problem is. I was googling how to replace CW filter and found this link:
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2

So I downloaded the operators manual and looked at page 34. Kenwood is perfectly clear about this. If the plug is in position A, the CW filter is bypassed.

I put the plug in position A and can tune to full power out in CW mode. If I place the plug in position B or C I get no power out when in CW mode.

Does this indicate a bad CW filter? The filter works fine in receive mode. The only thing I have noticed is that if I switch from USB to CW the signal drops 1 S-unit when peaked for max signal in both modes.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

At this point I am using my scope with 1 meg input. If is become suspicious of the reading I switch the 10X on and take the reading that way.

An immediate problem I see is I only have 10mV P-P at the drain of Q1 in FSK mode and 0 output in CW mode. The diagram says there should be 250 mV rms there. If I pull the CW filter out of the radio, how does the CW transmit work? Does the signal then go through the USB filter or do I need to install a jumper where the CW filter was?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Yes they are RMS.

I take them at around 14.175 to 14.200 mhz with the Car Level pot advanced to the point that with the Drive Control adjusted for a peak in ALC indication at panel meter full scale deflection. Then switch to CW mode and load to approx 100 watts out and turn off SG switch. Leave Car Level and Drive control alone.

Measured values will vary depending on what test instrument you are using, length of any test jumper leads used to access the test points, line voltage.

For example 8.830mhz TIF output at the IF board and input at the RF board is shown as 0.038v. This is 38.0 mv rms rf volts or 38 x 2.828 = 107 mv P-P. So if you have approx 100mv P-P TIF you are good.

Output of the TX Mixer is 1.4v rms or 4.0v P-P. This RF drive level is now 14.175 mhz.

If you plan on doing a lot of this work suggest you invest in a RF Millivolt meter. I use a Boonton 92E. I find it loads the circuits less and just easier and faster to use.

Of coures once you get to the 1.4 volts at output of the TX Mixer the old fashioned RF probe and VTVM works great. Just have to use multi-diode probe at plate of Driver tube and control grids of the Finals. I used a Heath 309C and PK-3 probes and a IM-18 VTVM for years and still have them for fall back.

Terry,

Are the transmit levels on page 42 of the service manual correct? Are those RMS values?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Thanks Terry. I have been talking to you since you have been helping. I don't know what made me put Dave on the last message (old age maybe).

I decided to start over from the beginning and go stage by stage this afternoon. This is what I did:
(All measurements taken with Send switch operated and Mode switch in CW position. Also, the measurements are the same in both CW and FSK modes.)

I suspected D1 or L1 was bad on the CAR-II board was bad but that is not the case. I have 720mV on CA2 leaving the CAR-II board in both CW and FSK send modes. I also have 720mV P-P on CA2 (IF5-13) on the IF board. I have 100mV P-P at the coax that connects to C92 on the IF board. On the other end of that coax where it connects to the top of T4 on the IF board I also have 100mV P-P. I would have thought the signal out of Q18 would have been stronger but maybe not.

I have 340mV at the junction of the cathode of D7 and C14 on the IF board. I have 280mV on the side of C14 where it feeds the CW filter. The signal going into the filter measures 8.830755 MHz. I only have 6mV P-P coming out of the crystal filter. Is the crystal filter used for transmit?

I connected the antenna to the radio and 20 meters is open. Tuning in CW signals in USB mode and switching to CW mode drops the signal by about 1 S-Unit when the signal is peaked for max signal in both modes.

Where do I go from here?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Are you talking Dave or Terry ? If someone is helping you off list I can back away as I have a pretty full plate right now.

I am not clear where you are measuring this 40mv P-P signal at?

Before I go I will mention that it is normal to not have a clean sine wave at TIF. It does have harmonic content and it is as you say due to LO mixing action. In this case it is coming from the VCO signal feeding back from the TX Mixer on RF board to the IF board.

This is easy to confirm with a TS-830 as you can easily unplug the VCO cable from the PLL board and the TIF signal will then be a nice clean 8.830mhz sine wave.

Dont worry about the complex waveform. Should still be able to get a reasonably close TIF measurement. It may not match exactly the levels on the TX Level Diagram,but you can compare it to the level you get with FSK carrier oscillator.

I dont use a O-scope to run TX Level diagrams once I get to the output of the TIF amp. I use a Boonton RF Millivolt meter and measure levels in rms and the "dirty" TIF signal presents no problem.

I have a new digital O-scope and it has a variety of digital filters. If I set it for a LP filter with a roll off frequency of 10mhz I can get a pretty clean 8.830 TIF sine wave display.

I dont know the Tek 2445 capability in this regard.

One final reminder is that good TIF signal level of approx 38mv rms or 107mv P-P is based on the premise that you accurately measured CA2 at the iF board of approx 300mv rms or 850mv P-P.

If that signal is not there then you would need to repeat the testing I asked you to do at the Carrier Osc board to confirm the 9vdc CW diode switching voltage is available at D1 and Q2 Buffer amp is being turned on.

I have been providing direction based on your reporting back that you have good CA

Ray:

Ok dinner is over and grand kids gone and house quiet. I need a beer!

Here is what I did to sweep the CW filter:

1. Removed the Carrier Osc metal cover 2 screws and exposed CAR-2 board
2. Removed small screw in center of the board.
3. Gently wiggled and pulled on the 10 pin Molex connector and removed the board
4. Connected RF Sig Gen output cable to pins 4 and 3 . Hot lead to 4 and shield to 3 or ground
5. Powered rig on in CW mode. Heaters and SG switch off. Drive control at 1200. VFO at 14.2mhz, and CAR Level pot full CCW.
6. Connected RF millivolt meter to IF board TP-5 and adjusted RF Sig gen output for 300mv rms @ 8830.70.
7. Connected RF millivolt meter to Diode D7 at input to the CW filter and flipped rig to Send and increased Car Level Pot for approx 30 mv input. Car Pot level was at position "2" for 30 mv carrier level. .
8. Moved RF millivolt meter to Diode D8 and swept the RF sig gen from 8800 to 9000. Found peak in RF voltage at approx 15 mv at 8830.689.

So the Fc of my filter is very close to 8830.70 and the attenuation closely matches what is listed on the TX Level Diagram.

Suggest you do not use much more than 30mv rms or 85 mv p-p input at Diode D7.

Ray

Apparently I am wrong about in situ sweeping of the CW filter by injecting inside Anode of D7 and measuring inside Anode of D8 and using no series source resistor at the input and no shunt load resistor at the output.

As I previously mentioned using these resistors is standard practice for testing crystal lattice filters on the bench. If you know the values of the internal input and output capacitors (not likely unless you are homebrewing the filters) there are formulas for calculating the resistance values absent knowing the factory impedance values. I have had good success using two resistor divider at input and output or using a pot to ground on each end and connecting the sig gen and rf measuring device to the wipers of the pots. Can then adjust the pots to get the optimum signal levels.

I had hoped this short cut method would show if the Fc had radically shifted and/or if there was an inordinate amount of signal attenuation.

I performed your test method on my TS820 CW filter early this am and the peak RF voltage occurred at 8830.52 and not 8830.70. By those results we would say my filter is bad and I know it is not as I get full CW output with it and my CA-2 carrier frequency is spot on 8830.7.

A couple of other in situ methods come to mind:

1. Rig powered off
2. Apply 12vdc from a dc bench supply or couple of lantern batteries to Molex Conn IF-2 Pins 4 and 5. This will turn on D7 and D8 filter switching diodes.
3. Inject test Rf signal at Cathode of D7 and measure the RF output at cathode of D8.

4. This method inserts the source and load resistance that the filter sees in operation.

OR

1. Rig powered on
2. Disable CA-2 8830.7 input to IF board
3. Inject test RF signal at TP-5
4. Measure RF output at cathode of D8.

I have a pretty full plate today so will think about this and perhaps after dinner tonite can try one or both of these above methods.

Ray

Much better got it all this time.

Yes the diode barrier voltages will vary as the dc supply and line voltage will also vary. As long at the diodes are the original silicon diodes then 0.6vdc to 0.7vdc is typical. You are looking for gross differences between what I read. I looked at your readings and I agree the diodes are fine and the switching voltage supply to them is there.

Yes for most accurate sweep should terminate filter input and output in its characteristic impedance, but for this test what you have should be OK as we are only interested in relative rf voltages. I dont know what the input/output impedance of this filter is. Most of the KW filters have impedances that range from 300 ohms to 2k ohms that I have seen. You could experiment and repeat test with resistor divider on each end.

When I sweep a KW filter out of the rig on the bench I look at service manual for the input/output impedance. I then make a 2 resistor divider at each side of the filter. For example if the filter Z is 600 ohms I will place a 600 ohm resistor in series with the filter input and a 50 ohm resistor in shunt to ground. I connect the sig gen to the free end of the 600 ohm series resistor. Do same at output and connect the O-scope or RF millivolt meter to the free end of the 600 ohm resistor.

You can see that if your CW TX carrier frequency is 8830.7 as it should be then it will be outside the -6dB bandpass of the filter if the measured FC is 8830.3.

I will try to get time tomorrow and sweep my filter in place using same method you employed for comparison.

What you know for sure is :
1. D7/D8 are being biased on in CW mode.
2. With .047 cap bridging the filter you get full RF output in CW mode
3. With cap removed no RF output

Sure looks like filter is the culprit.

You are doing some good work here. Absent test gear, knowing how to use it, ability to read a schematic, and some familiarization with the board layouts this is a challenging task for any hybrid owner.

I will get back with my sweep results.

Terry,

Let me try again. The unreadable post has been happening a lot since Yahoo went to this new format last month.

With the .047 cap on the anodes of D7 and D8 I am able to obtain full output in CW mode. Also, both diodes are forward biased in CW Send mode as I see approximately .6 volts drop across them in Pos C. The voltages are about .1 volt lower than what you are showing.

Do you know the impedance of the crystal filters in the TS-820? This is the signal source I have to use to test with:
http://www.oocities.org/hagtronics/source/index.html
It has a 50 ohm output. I also have a HP 3314A I could use but it is also 50 ohms out.

With the signal source set to -1 dB out and in and out connections at the anodes of D7 and D8, I get these are the readings I get:
8.8300 - -46.9 dB
8.8301 - -33.3 dB
8.8302 - -19.5 dB
8.8303 - -14.4 dB
8.8304 - -17.5 dB
8.8305 - -26.4 dB
8.8306 - -28-5 dB
8.8307 - -42.5 dB
8.8308 - -49.5 dB
8.8309 - -49.7 dB
8.8310 - -50.0 dB

The filter FC appears to be at 8.8303. My scope with 1 meg load agrees with this as I see the peak on it at the same frequency. I don't know how much the 50 ohm generator and power meter loads are affecting the filter.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray that is because you have the test cap on the Cathode sides of D7 and D8. Move the cap to the Anode sides of each and the plug to Pos C. Now you are checking the diodes as well.

This test proves that you have sufficient RF carrier level from the BM available at the Cathode of D7 to produce full output in CW.

Problem is if jumpering the filter works then which is bad? The CW filter or one or both diodes or the bias supply to the diodes?

I would focus all my efforts with the plug in Pos C to simplify reading taking.

In Pos C you need to ensure that each diode is forward biased.

D7 Cathode = 2.85vdc
D7 Anode = 2.25vdc

D8 Cathode = 9.8vdc
D8 Anode = 9.2vdc

Pretty sure you have already done this and confirmed you have diode supply voltage and good diodes so that just the filter.

Do you have an RF sig generator? If you do you can sweep the filter. It will tell you couple of things.
1. Where is Fc at (center frequency)
2. What is its attenuation

Doesnt have to be a sophisticated or accurate RF sig gen.

Can set it at around 8.0 mhz as measured by your Simpson Freq counter and set the rf output level to approx 200mv as measured by your O-scope.

Connect the output from RF sig gen to Anode of D7 and your O-scope at Anode of D8 (rig power is off) and slowly raise the frequency and see where the peak RF output voltage occurs at. Should be close to 8830.7khz. This assumes your sig gen output voltage doesnt vary greatly for small change in frequency. If it does you would need two ways to measure RF so you could ride the sig gen output to keep it constant.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry, with a .047 capacitor across the CW filter, I get full output in CW mode regardless of what position the IF2 connector is in.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

These are the readings taken with IF2 connector in all three positions (P-P values):
Position A: D7 cathode: 800mV CW, 800 mV FSK --- D8 cathode: 600mV CW, 400mV FSK
Position B: D7 cathode: 600mV CW, 800 mV FSK --- D8 cathode: 44mV CW, 400 mV FSK
Position C: D7 cathode: 260mV CW, 800 mv FSK --- D8 cathode: 40mV CW, 400 mV FSK
All readings were taken with my scope with the probe in the 10X position to prevent loading of the circuit.

These are the DC readings for D7 and D8 in all three positions (RMS values):
Position A: CW - D7 anode: -3.6V, cathode: 2.0V -- D8 anode: 0V, cathode: 9.0V
Position A: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode 8.5V
Position B: CW - D7 anode: 2.8V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.7V
Position B: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode: 8.5V
Position C: CW - D7 anode: 2.8V, cathode: 2.2V -- D8 anode: 9.3V, cathode: 8.6V
Position C: FSK - D7 anode: 2.7V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.6V

The only position I get output in CW mode is when the connector is in position A.

The CW filter is a TRIO YG-88C and I have re-soldered all connections on the filter.

I meant Cathode voltages but I think you get the idea. Measure the Anode and Cathode to ensure both diodes are being switched on. Should see approx 0.65 vdc drop across D7 and D8 as they are silicon diodes.

Not likely bad but if you need to replace I offer the following:

Should you need a diode do not use a NTE 177 sub. These are 1S1587 fast switching diodes with a fast reverse recovery time of approx 2 ns so I would not use a general purpose silicon diode as NTE sub guide suggests. Can use a NTE 519, but it has a recovery time of approx 70 ns.

I think a 1N914 or 1N4148 would be better choice at 4ns..These are still pretty commonly available.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK I forgot to give you the Anode voltages of D7 and D8 but you can just subtract approx 0.65vdc for the turn on voltage.

280mv P-P is high by my measurements, but if you read close to same in FSK-T then call it good. Certainly better than be too low.

6 mv P-P at output in CW-T is definitely a problem. As I said you can jumper the filter with a .047uf cap and see if you get CW Tx.

Is this the factory YG-88C filter?

I believe it has center frequency of 8830.7 mhz.and bandwidth of 500hz at -6dB.
I have never swept one.

It would not seem likely that you would have bad solder connections if the filter is working in FSK mode. Are you 100% certain you are not using the SSB filter in FSK mode?

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

My voltages at D7 and D8 are virtually identical to yours. I had previously measured the levels at D7 and D8. I measured 280mV P-P where C14 connects to the CW filter and only 6mV P-P out of the filter. But that was before I changed the cable to position A. I will have to move the cable back to C and re-measure tomorrow. I will also pull the IF board out and resolder the CW crystal filter connections. It may be bad solder connections as you suggest.

I just made my first contact in 17 years on 7.020 with W5TZC about 30 mins ago. He gave me a 579 which is pretty good considering my antenna is only 8 feet off the ground. I also

still have to address why they final isn't tuning properly on 40 meters. It tuned max power with plate knob pointer sitting on the 5 of 3.5. It dips at 14 on 20 meters.

If I can get the CW filter issue worked out I will go through a complete tuneup of the radio following the service manual procedures.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

It is easy to test CW filter switching diodes D7 and D8. I thought you already did this and reported good?

As previously noted my plug is in C all the way toward the front panel.

Conn IF-2 pins 4 and 5 have approx 12.9vdc on them in Rx and Tx for CW-R, CW-T, FSK-R, and FSK-T.

The cathode of D7 is:
CW-R and FSK-R = 2.90vdc
CW-T and FSK- T = 2.90vdc

The cathode of D8 is : (Note: When you connect voltmeter back ground noise will drop significantly).
CW-R and FSK-R = 10.0vdc
CW-T and FSK-T = 9.80vdc

The reading will be different as the diodes are biased to different current levels. You can see the difference in the supply resistors for each diode.

I have never been able to measure TX level diagram RF voltages accurately using a 1X scope probe. It will pull your ALC indication down from FSD (40 over) to approx 25 over.

You should be able to measure the 8.830mhz TIF signal level at the input and output of the CW Xtal filter. I thought we did this a long time ago?

It is normal for the filters to have an insertion loss. Should have a minimum of approx 25mv rms at D7 input and minimum of approx 19mv rms at D8 output.

Here are my RF level measurements at D7 and D8:

Test conditons: 14.175mhz, Heater on , SG switch off, CW mode, Drive control peaked, Car Pot at 2.5 (for full scale ALC deflection or 40 over)

Boonton 92E (using 10x scope probe very close to same levels)
D7 = 58mv
D8 = 25mv

You can jumper across your CW filter with a couple of mini-grabber test leads with a 0.047uf capacitor in series.

Could have good switching diodes and good filter but bad solder connections at the filter?

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I have made a discovery that will probably tell us where the actual problem is. I was googling how to replace CW filter and found this link:
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2

So I downloaded the operators manual and looked at page 34. Kenwood is perfectly clear about this. If the plug is in position A, the CW filter is bypassed.

I put the plug in position A and can tune to full power out in CW mode. If I place the plug in position B or C I get no power out when in CW mode.

Does this indicate a bad CW filter? The filter works fine in receive mode. The only thing I have noticed is that if I switch from USB to CW the signal drops 1 S-unit when peaked for max signal in both modes.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

At this point I am using my scope with 1 meg input. If is become suspicious of the reading I switch the 10X on and take the reading that way.

An immediate problem I see is I only have 10mV P-P at the drain of Q1 in FSK mode and 0 output in CW mode. The diagram says there should be 250 mV rms there. If I pull the CW filter out of the radio, how does the CW transmit work? Does the signal then go through the USB filter or do I need to install a jumper where the CW filter was?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Yes they are RMS.

I take them at around 14.175 to 14.200 mhz with the Car Level pot advanced to the point that with the Drive Control adjusted for a peak in ALC indication at panel meter full scale deflection. Then switch to CW mode and load to approx 100 watts out and turn off SG switch. Leave Car Level and Drive control alone.

Measured values will vary depending on what test instrument you are using, length of any test jumper leads used to access the test points, line voltage.

For example 8.830mhz TIF output at the IF board and input at the RF board is shown as 0.038v. This is 38.0 mv rms rf volts or 38 x 2.828 = 107 mv P-P. So if you have approx 100mv P-P TIF you are good.

Output of the TX Mixer is 1.4v rms or 4.0v P-P. This RF drive level is now 14.175 mhz.

If you plan on doing a lot of this work suggest you invest in a RF Millivolt meter. I use a Boonton 92E. I find it loads the circuits less and just easier and faster to use.

Of coures once you get to the 1.4 volts at output of the TX Mixer the old fashioned RF probe and VTVM works great. Just have to use multi-diode probe at plate of Driver tube and control grids of the Finals. I used a Heath 309C and PK-3 probes and a IM-18 VTVM for years and still have them for fall back.

Terry,

Are the transmit levels on page 42 of the service manual correct? Are those RMS values?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Thanks Terry. I have been talking to you since you have been helping. I don't know what made me put Dave on the last message (old age maybe).

I decided to start over from the beginning and go stage by stage this afternoon. This is what I did:
(All measurements taken with Send switch operated and Mode switch in CW position. Also, the measurements are the same in both CW and FSK modes.)

I suspected D1 or L1 was bad on the CAR-II board was bad but that is not the case. I have 720mV on CA2 leaving the CAR-II board in both CW and FSK send modes. I also have 720mV P-P on CA2 (IF5-13) on the IF board. I have 100mV P-P at the coax that connects to C92 on the IF board. On the other end of that coax where it connects to the top of T4 on the IF board I also have 100mV P-P. I would have thought the signal out of Q18 would have been stronger but maybe not.

I have 340mV at the junction of the cathode of D7 and C14 on the IF board. I have 280mV on the side of C14 where it feeds the CW filter. The signal going into the filter measures 8.830755 MHz. I only have 6mV P-P coming out of the crystal filter. Is the crystal filter used for transmit?

I connected the antenna to the radio and 20 meters is open. Tuning in CW signals in USB mode and switching to CW mode drops the signal by about 1 S-Unit when the signal is peaked for max signal in both modes.

Where do I go from here?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Are you talking Dave or Terry ? If someone is helping you off list I can back away as I have a pretty full plate right now.

I am not clear where you are measuring this 40mv P-P signal at?

Before I go I will mention that it is normal to not have a clean sine wave at TIF. It does have harmonic content and it is as you say due to LO mixing action. In this case it is coming from the VCO signal feeding back from the TX Mixer on RF board to the IF board.

This is easy to confirm with a TS-830 as you can easily unplug the VCO cable from the PLL board and the TIF signal will then be a nice clean 8.830mhz sine wave.

Dont worry about the complex waveform. Should still be able to get a reasonably close TIF measurement. It may not match exactly the levels on the TX Level Diagram,but you can compare it to the level you get with FSK carrier oscillator.

I dont use a O-scope to run TX Level diagrams once I get to the output of the TIF amp. I use a Boonton RF Millivolt meter and measure levels in rms and the "dirty" TIF signal presents no problem.

I have a new digital O-scope and it has a variety of digital filters. If I set it for a LP filter with a roll off frequency of 10mhz I can get a pretty clean 8.830 TIF sine wave display.

I dont know the Tek 2445 capability in this regard.

One final reminder is that good TIF signal level of approx 38mv rms or 107mv P-P is based on the premise that you accurately measured CA2 at the iF board of approx 300mv rms or 850mv P-P.

If that signal is not there then you would need to repeat the testing I asked you to do at the Carrier Osc board to confirm the 9vdc CW diode switching voltage is available at D1 and Q2 Buffer amp is being turned on.

I have been providing direction based on your reporting back that you have good CA

G'day,

Go with the solder method if you really want a good job. But as Terry suggests give the wafer switches on the RF boad a real good clean, you'll be amazed at how successful this is. Only other thing I can suggest is the last two wafer boards nearest to PA, have a very good close look at the fingers, these can twist or loose tension and if a small amount of grit/dirt gets in between then you have issues. No point in pulling the RF board out if you don't have to, do the simple things first as you can always do the more techically challenging things a a later time.

I do as Ken Kemski, does pull the board then throw it in the sink with soapy water, light scrub with tooth brush. I then shake\flick dry then risk life and limb in borrowing XYLs hair dryer and dry off the board really well. If you get caught using hairdryer, please don't mention me, LOL. Have had great success with this method

73's

Dave

Subject: [TS-520_820_530_830] RE: No ALC on 12 meters....

They are talking about the silver conductive pen repair method described on Ken K4EAA web site.

I dont silver anymore. I solder small wires from the window of the hair pin loop to the PC traces being careful not to use too much heat to hurt the spring temper.

Either method cannot be done in place. It is a major job. Look at the pictures on Kens website.

Dick W0NTA has lots of experience with the jumper method. Might write him and ask for any tips. I very good de-soldering tool really helps and much less chance of lifting a foil. Hakko 808 gun is about best I have ever used, but like all tools comes at a price. It can be done with solder wick. .

I would be 100 percent certain if it is bad bandswitch contact before pulling the RF board.

Did you try applying some Deoxit? Use artist brush, Q-tip, tooth pick and apply sparingly. Exercise and blow out with canned air.

Terry K9TW

Yes, the question of ALC is the most confusing to me. As you say, there are many of people that do various things to keep the meter within the black ALC range. A new driver tube with CAR set in the middle goes way past the ALC range on the meter. Do I then lower CAR to not go past this range, or you said it doesn't matter, and I just peak with the DRIVE control with CAR at center no matter where the meter goes???? I feel I'm destroying my driver tube and not knowing it because the manual doesn't show you what you should see, or what is optimal when you are doing the ALC step.

My understanding is that it is maximum meter deflection. In other words, you turn the DRIVE control until the needle doesn't go any higher... yes, no?? What you are looking for is the opposite of what you look for when you dip the PLATE?

Sorry, but all this is new to me and I'm learning as I'm going. The manual is not that straight forward and assumes a certain knowledge that was probably very common when this radio was made. Not so common now with all the solid state, turn on and play rigs.

Even K4EAA, has a different tuning procedure than what the manual defines. I cannot find an Elmer in my area that knows about these rigs, at least I haven't found someone yet.

If anyone wants to give me a call and explain some of this in more detail, call me at 559-272-6759. I'm in Pacific Standard Time, and usually up and about until after 11:00PM.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

There is no SSB loading procedure in any TS830 operating manual that I have seen and no way to load with Mode Switch in LSB or USB unless you inject audio in to the mic jack? Dont know what manual you were reading.

There is Step 4.3 Transmission that clearly describes how to load the TS830 and that is done in CW mode. At Step 9 in clearly states you are now done and fully loaded and ready for CW operation. Need to go on to the CW section to learn how to zero beat but loading is done.

If you had literally followed this Step 4.3 you would not have turned your Car Level Pot back CCW at its conclusion. Where did it direct you to do that?

Only thing they could have added is if you want to run less than 100 watts out you can reduce the Carrier Level pot position to any output power level you desire. Apparently that is not intuitive.

Some points of clarification:

1. Manual says to check resting plate current and set to 60ma. No need to do that every time you load the rig. OK to do, but not required. Once set should not change for a long time. If rig is new to you then should clean the bias voltage adjust pot on rear panel with deoxit and blow out with canned air and adjust for 60ma. You are setting the zero signal

operating point (Class AB1).

2. Almost everyone has a question about Step 5 adjusting the Drive control to peak the ALC indication. What ALC peak? Do they mean the printed black rectangular box or the full scale of the panel meter? IT DOES NO MATTER. You are not reading any of the meter scales. You are NOT setting grid current levels. You are adjusting the Transmit Mixer and Transmit Drive tuned circuits for resonance so you will have maximum RF drive (voltage swing) at the control grids of the 6146 finals. Videos will go to great length to show that you must keep ALC indication in the center of the black printed range or at the far right edge of it and to go back and check it after loading and if not to adjust it. All of this is bogus and shows no understanding of what this step is. Some of this comes from long time hams. Just advance the Car Level pot to get a decent indicated level that you can peak. If the level of carrier pegs the meter simply back the Car Pot down a little.

3. After adjusting the Plate Tune cap for a dip in Plate current (Ip) in Tune mode all the KW hybrid manuals have you flip meter to RF Relative Power position to load to maximum relative power output and as a last step go back to Ip meter position to make sure not exceeding maximum plate dissipation. 200ma for the 520/820 rigs and 265ma for the 530/830 rigs. Most 530/830 owners do not load much above 225ma in effort to extend tube life.

No where does KW recommend you load the radio using the plate current Dip and Load method. Old timers do this as they learned it from Class C grid leak bias CW transmitter days. It was only game in town as there were no external wattmeters and they had to watch grid current so they didnt exceed 6146 final tube control grid dissipation and damage the tubes. None of that applies to a KW Hybrid. It is a Class AB1 linear amp. For this reason KW gave you the RF Relative Power meter position to load the radio. In Class AB1 loading to max rf output without exceeding max plate dissipation will result in the max load (best efficiency) occurring slightly to inductive side of true resonance. Hard to see the actual minimum dip in Class AB1 tetrode amps.

4. For all new folks I suggest that since you need a SWR bridge to trim your dipoles do yourself a favor and buy a wattmeter like a Drake W4 or Heath HM-102 and you now have your SWR bridge and a KW hybrid loading aid and test meter. Instead of using the RF meter position leave rig meter in IP and load for maximum RF output power on the external wattmeter (this will be approx 100 watts out or a little less) without exceeding approx 200 to 225 ma. 225ma is a level that Ken K4EAA recommends to ensure long tube life. It is not a hard number.

Using the Wattmeter gives a real power number to look at and simplifies loading and gives instant indication of problems with the rig or your antenna system. These are problems that you as a new person would not likely recognize or understand looking at the Ip meter indication.

Loading one of these radios can be accomplished literally in seconds.

If you pre-set the controls can be done even in CW mode to get that initial plate current dip. Not recommended until you gain some experience.

I have seen no You Tube videos that I would recommend. Most are flawed especially when it comes to peaking the ALC indication and that includes those posted by Extra class holders. Lots of good intentions and little technical understanding of what is happening on the ends of the control knob shafts.

Until you gain some knowledge and experience if you can read, read with comprehension, and observe literal procedure compliance, then the loading procedure steps in all the manuals works just fine.

Tell me about it !
I am a CW operator normally at QRP.

So, I decided to put the Kenwood 830 'on line'.
I went through the whole SSB tuning sequence,
because that is all that was in my manual.
Then at the end they state something like
flip the switch to CW and you are ready to go.
NOT !
The SSB procedures have just canceled out your Carrier,
thus NO CW signal.

I thought I missed something, so I went back through all this several times.

Finally, I just rotated the Carrier Knob and gave myself some Carrier for the CW signal.

All went well after that.

Anyway, Kenwood 830 is a 1985 Cadillac of transceivers.
Glad to have one.
You just have to have more experience than the guy who wrote the manuals.

This is a good Group and the chatter about Kenwood topics is informative.
No magic, but good advice.

Thanks guys.

G'day,

Turn heaters on and allow a few minutes for the tubes to warm up and get to operating stage.

Turn mode switch to tune and a dummy load and external watt meter connected.

place the plate marker to the band your going to tune on and the load control fully counter clockwise.

Meter switch to ALC

Flick send switch and peak the drive control, if the needle goes out of the ALC range use the carrier control to back it off until it is at maximum position of the ALC mark

switch meter to IP, then dip the needle using the plate control

switch meter to RF and then using the load control peak the needle

Send switch to rec position

mode switch to cw, either wide or narrow your choice.

flick send switch to send

Very quickly and I mean quickly while watching the watt meter, peak the output using the plate and load control, this should take no more than a few seconds, if your not able to do it in one go due to limited experience flick send switch back to rec for a few minutes.

Repeat this until you get maximum output, if you have low output then try and turn your carrier pot clock wise, you will see the output rise, on all of my 530s and 830s radios my car is set to less that half of the potentiometer's travel and this is subject to band being tuned.

This will take a few attempts but once mastered you will be able to tune within the 5 second timeframe.

The benefit of having an external watt meter is so you can easily see that you have maximum output and have the PA tuned properly thus taking a heap of pressure of you tubes and associated parts in the PA and final board.

Once your happy with output, turn send switch to receive, mode switch to USB\LSB, mic gain to about 10 o'clock position, meter to ALC, speak into mic and see if the meter moves in the ALC. Now if you have ALC movement back the mic gain off (CCW) until the ALC needle just moves, this will ensure you have good clean audio, check the output with whislt talking and if you want use a whistle unless of course you have a two tone generator.

/*Ignore*/ the ALC scale during TUNE mode adjustment of the DRIVE control for a peak meter "pointer" indication! If the meter pegs full scale to the right while adjusting the DRIVE control, simply adjust the CAR control CCW for a "reduction" in the meter "pointer" indication then continue adjusting the DRIVE control for a peak meter "pointer" indication, again, ignoring the ALC scale!

The driver and/or final tubes are NOT being damaged if the TUNE mode DRIVE control peak adjustment results in the meter "pointer" resting outside the top end of the ALC scale. Where did you get the idea the tubes are being damaged if the meter pointer, after achieving a DRIVE control peak adjustment indication in TUNE mode, rests outside the top end of the ALC scale?

Barry:

I dont know how to say it any plainer the ALC indication level DOES NOT MATTER.
You can chose to believe me or not.

One exception is dont set it too low. Can be very touchy if too low and fall back to zero. Give yourself something to work with and if setting it to the top end of the black box gives you some comfort by all means do so. It is a perfect spot to see the peak.

You will not hurt your Driver Tube or the 6146 Final Tubes at this step in the loading procedure. Cannot exceed Driver Tube dissipation unless you leave rig in SEND position and walk away. I thought I made that very clear what you are doing. You are adjusting the Mixer and Drive parallel resonant tuned circuits to resonance which means maximum RF drive voltage swing available for the 6146 final tube grids which is what you need for maximum RF output to your dummy load or antenna.

Yes a peak is the opposite of a null or a dip in a meter indication.

A peak means you adjust the Drive Control for the maximum meter pointer deflection. For this reason you cannot have so much Carrier Level that the meter goes off the far right hand end of the meter scale. They call this FSD or full scale deflection. If the meter indicator was there you cannot see a peak.

So just give yourself enough indication (2/3 scale is fine) to see that when you adjust the Drive Control that the meter indicator will rise and then fall as you tune thru resonance. A well aligned rig this peak will occur pretty close to 1200 on the Drive Control knob with VFO at middle of its frequency range (200 to 250)

You will not hurt your Driver tube unless you flip to Send and leave it keyed a very long time. It only takes a few seconds (no more than 5 to 10 seconds) to peak the ALC indication. When you return the Send switch back to Receive or stand-by position the Driver tube is cut off and no plate current flows.

The Tune position is provided so that you can do the next step safely without damaging the 6146 final tubes. It cuts the screen grid voltage in half for the 6146 finals. What you are next doing in TUNE mode is "dipping" the plate current. Here you are adjusting the Pi-Network which serves as the parallel resonant tuned circuit in the Plate circuit of the 6146 tubes. If you have pre-set the Plate Tune control close to the white mark you will see very little dip maybe 5 to 10 ma. If it is set far away maybe 40 to 50 ma of dip.

You never want to leave the Pi-Network (called the Tank circuit) in an off resonant state for a long time as heavy plate current will flow and can exceed the plate dissipation of the tube ie overheat it. So in Tune mode you are limited to approx 100ma of plate current and can have longer key down times without damaging the tubes.

In TUNE mode and meter now switched from ALC to IP position you Flip to Send and adjust the Plate Tune control for a "dip" or "null" in the meter indication. You have now adjusted the

Tank circuit to resonance.

Need to do this step fairly quickly. Again 5 to 10 seconds is more than adequate.

Once you have Peaked the Drive and adjusted the Tank to resonance in TUNE mode you are ready now to place meter in RF position and CW mode and adjust Plate Load and Plate Tune for maximum indication on the meter. If meter pegs off scale have to adjust the RF sensitivity pot to bring it back on scale. Again none of the scales mean anything. It is just a sample of the RF voltage available at your SO-239 connector output to the dummy load. Again keep this step short and if experiencing problems unkey the rig and let it rest a few seconds.

If you are still struggling let me know and I will call you.

Terry K9TW

Yes, the question of ALC is the most confusing to me. As you say, there are many of people that do various things to keep the meter within the black ALC range. A new driver tube with CAR set in the middle goes way past the ALC range on the meter. Do I then lower CAR to not go past this range, or you said it doesn't matter, and I just peak with the DRIVE control with CAR at center no matter where the meter goes???? I feel I'm destroying my driver tube and not knowing it because the manual doesn't show you what you should see, or what is optimal when you are doing the ALC step.

My understanding is that it is maximum meter deflection. In other words, you turn the DRIVE control until the needle doesn't go any higher... yes, no?? What you are looking for is the opposite of what you look for when you dip the PLATE?

Sorry, but all this is new to me and I'm learning as I'm going. The manual is not that straight forward and assumes a certain knowledge that was probably very common when this radio was made. Not so common now with all the solid state, turn on and play rigs.

Even K4EAA, has a different tuning procedure than what the manual defines. I cannot find an Elmer in my area that knows about these rigs, at least I haven't found someone yet.

If anyone wants to give me a call and explain some of this in more detail, call me at 559-272-6759. I'm in Pacific Standard Time, and usually up and about until after 11:00PM.

Barry (K0DDR)

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

There is no SSB loading procedure in any TS830 operating manual that I have seen and no way to load with Mode Switch in LSB or USB unless you inject audio in to the mic jack? Dont know what manual you were reading.

There is Step 4.3 Transmission that clearly describes how to load the TS830 and that is done in CW mode. At Step 9 in clearly states you are now done and fully loaded and ready for CW operation. Need to go on to the CW section to learn how to zero beat but loading is done.

If you had literally followed this Step 4.3 you would not have turned your Car Level Pot back CCW at its conclusion. Where did it direct you to do that?

Only thing they could have added is if you want to run less than 100 watts out you can reduce the Carrier Level pot position to any output power level you desire. Apparently that is not intuitive.

Some points of clarification:

1. Manual says to check resting plate current and set to 60ma. No need to do that every time you load the rig. OK to do, but not required. Once set should not change for a long time. If rig is new to you then should clean the bias voltage adjust pot on rear panel with deoxit and blow out with canned air and adjust for 60ma. You are setting the zero signal operating point (Class AB1).

2. Almost everyone has a question about Step 5 adjusting the Drive control to peak the ALC indication. What ALC peak? Do they mean the printed black rectangular box or the full scale of the panel meter? IT DOES NO MATTER. You are not reading any of the meter scales. You are NOT setting grid current levels. You are adjusting the Transmit Mixer and Transmit Drive tuned circuits for resonance so you will have maximum RF drive (voltage swing) at the control grids of the 6146 finals. Videos will go to great length to show that you must keep ALC indication in the center of the black printed range or at the far right edge of it and to go back and check it after loading and if not to adjust it. All of this is bogus and shows no understanding of what this step is. Some of this comes from long time hams. Just advance the Car Level pot to get a decent indicated level that you can peak. If the level of carrier pegs the meter simply back the Car Pot down a little.

3. After adjusting the Plate Tune cap for a dip in Plate current (Ip) in Tune mode all the KW hybrid manuals have you flip meter to RF Relative Power position to load to maximum relative power output and as a last step go back to Ip meter position to make sure not exceeding maximum plate dissipation. 200ma for the 520/820 rigs and 265ma for the 530/830 rigs. Most 530/830 owners do not load much above 225ma in effort to extend tube life.

No where does KW recommend you load the radio using the plate current Dip and Load method. Old timers do this as they learned it from Class C grid leak bias CW transmitter days. It was only game in town as there were no external wattmeters and they had to watch grid current so they didnt exceed 6146 final tube control grid dissipation and damage the tubes. None of that applies to a KW Hybrid. It is a Class AB1 linear amp. For this reason KW gave you the RF Relative Power meter position to load the radio. In Class AB1 loading to max rf output without exceeding max plate dissipation will result in the max load (best efficiency) occurring slightly to inductive side of true resonance. Hard to see the actual minimum dip in Class AB1 tetrode amps.

4. For all new folks I suggest that since you need a SWR bridge to trim your dipoles do yourself a favor and buy a wattmeter like a Drake W4 or Heath HM-102 and you now have your SWR bridge and a KW hybrid loading aid and test meter. Instead of using the RF meter position leave rig meter in IP and load for maximum RF output power on the external wattmeter (this will be approx 100 watts out or a little less) without exceeding approx 200 to 225 ma. 225ma is a level that Ken K4EAA recommends to ensure long tube life. It is not a hard number.

Using the Wattmeter gives a real power number to look at and simplifies loading and gives instant indication of problems with the rig or your antenna system. These are problems that you as a new person would not likely recognize or understand looking at the Ip meter indication.

Loading one of these radios can be accomplished literally in seconds.

If you pre-set the controls can be done even in CW mode to get that initial plate current dip. Not recommended until you gain some experience.

I have seen no You Tube videos that I would recommend. Most are flawed especially when it comes to peaking the ALC indication and that includes those posted by Extra class holders. Lots of good intentions and little technical understanding of what is happening on the ends of the control knob shafts.

Until you gain some knowledge and experience if you can read, read with comprehension, and observe literal procedure compliance, then the loading procedure steps in all the manuals works just fine.

Too many sissies today. We arent kindergarten kids getting "dissed". We are adults. My self esteem is just fine. My time is worth something and wont waste it on the "cants or wonts".

You havent see mean spirited here.

People can choose to accept and follow the advice or not. Dont expect blind obedience, but when I take the time to tell someone that setting the ALC peak indication at a particular level DOES NOT MATTER and then take the time to explain why in as simple a terms as I know how and they come back and ask me again if it matters I dont know how to answer that anyway other than restating it again in as firm a manner as I can without "dissing" the person or destroying their fragile self esteem.

I propose you let him speak for himself. He can let me know if his feelings are hurt.

I did not ask him if he had a reading comprehension problem.

I dont need a lecture from someone who makes no meaningful contributions or has no clue how the radio works.

Dave:

I forgot one thing.

It would be better to hear from the OP if he were to say something like..... "OK Terry I heard your response and I appreciate your advice, but now I would like to hear from others on this subject and will decide my operational practice based on the groups consensus".

I would be OK with that as he would be doing his due diligence. However, there can be risk in following the herd knowledge base and common practice as tribal myths abound in this hobby. It is a challenge to sort out the BS from the facts. Wait until you get cancer and Google on best course of action!

Fortunately in this case opinions and common practice does not mean a thing. The Op can peak the ALC indication anywhere he chooses and he will not damage his new Driver tube unless he leaves rig keyed and goes to lunch.

As they say IMO.

Terry K9TW

Thanks for the tutorial. Very helpful.
I missed something in the SSB tune-up.

Am using an Antenna Tuner with calibrated Power Meters,
which work with the Knwd 830 "RF" meter relative readings.
That is a double-check against accidently overpowering.

On the Knwd 830, Currently, when changing bands,
1) I set the "Carrier" to the CW #6 or #8.
which produces maybe a 1 W Power Forward at the Antenna Tuner.
2) I begin adjusting Load / Plate / Drive, watching the "IP" and the Tuner Pwr.
I adjust the "Carrier" CCW towards #5 , then #4,
which gradually increases the Power Forward reading in the Antenna Tuner.
3) Back and forth a few times, to get 100 mA "IP" and 25 W Power Forward.
This allows me to sharply tune the antenna.
4) Lastly, I typically I back off towards 5 W Power Forward.

Other than the trusty HW8,
my former experience was with an ARC-5 running pair of 807 at 205 W.
Careful drive and tuning was required else the 807's would turn yellow !

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

G'day,

Turn heaters on and allow a few minutes for the tubes to warm up and get to operating stage.

Turn mode switch to tune and a dummy load and external watt meter connected.

place the plate marker to the band your going to tune on and the load control fully counter clockwise.

Meter switch to ALC

Flick send switch and peak the drive control, if the needle goes out of the ALC range use the carrier control to back it off until it is at maximum position of the ALC mark

switch meter to IP, then dip the needle using the plate control

switch meter to RF and then using the load control peak the needle

Send switch to rec position

mode switch to cw, either wide or narrow your choice.

flick send switch to send

Very quickly and I mean quickly while watching the watt meter, peak the output using the plate and load control, this should take no more than a few seconds, if your not able to do it in one go due to limited experience flick send switch back to rec for a few minutes.

Repeat this until you get maximum output, if you have low output then try and turn your carrier pot clock wise, you will see the output rise, on all of my 530s and 830s radios my car is set to less that half of the potentiometer's travel and this is subject to band being tuned.

This will take a few attempts but once mastered you will be able to tune within the 5 second timeframe.

The benefit of having an external watt meter is so you can easily see that you have maximum output and have the PA tuned properly thus taking a heap of pressure of you tubes and associated parts in the PA and final board.

Once your happy with output, turn send switch to receive, mode switch to USB\LSB, mic gain to about 10 o'clock position, meter to ALC, speak into mic and see if the meter moves in the ALC. Now if you have ALC movement back the mic gain off (CCW) until the ALC needle just moves, this will ensure you have good clean audio, check the output with whislt talking and if you want use a whistle unless of course you have a two tone generator.

Hello everyone. Sorry if my questions were upsetting, I didn't mean it that way, and was certainly not trying to offend anyone by attempting to reconfirm my understanding and to gain a little bit more understanding of the mechanics of this radio. If my posts seemed sarcastic or mocking to you Terry, then they were taken in the wrong way.

I'm not hurt or offended by Terry or anyone else, and I certainly appreciate Terry's confirmation that the ALC position does not matter and everything else he shared. It removes my doubts based on what I have read and seen through other sources, which made it seem that the position was critical. Lots of great information and explanation of the mechanics behind this radio in these posts, so I'm learning. Call me stupid, ignorant, or whatever... I can ignore that and collect the nuggets of great knowledge that is also shared at the same time. You need a tough hide to play on the Internet.

A phone conversation can be so much easier in many cases in the transfer of information. That is why I suggested it, but I'll take what I can get.

However, I'm pretty sure I understand now, and much has been clarified and I feel more confident.

Until my next question... 73!

I forgot one thing.

It would be better to hear from the OP if he were to say something like..... "OK Terry I heard your response and I appreciate your advice, but now I would like to hear from others on this subject and will decide my operational practice based on the groups consensus".

I would be OK with that as he would be doing his due diligence. However, there can be risk in following the herd knowledge base and common practice as tribal myths abound in this hobby. It is a challenge to sort out the BS from the facts. Wait until you get cancer and Google on best course of action!

Fortunately in this case opinions and common practice does not mean a thing. The Op can peak the ALC indication anywhere he chooses and he will not damage his new Driver tube unless he leaves rig keyed and goes to lunch.

As they say IMO.

Hi Bob
Was wondering first of all would you be willing to send parts to England, If so would you please give me a price on the Assembly that holds the Drive Ant Mixer and Osc coils, (Located on the underside of the rig on the band change switch) If required will give you the part number.
My radio is a TS520s that is need of lost of restoration but these boards are the most urgent
Thanks
Peter G8ZZL

45578. Requests for Help

Yahoo group: TS-520_820_530_830 (2013-08 — 2013-12)
Date: 2013-10-30 18:24:21 UTC
From: Bob Lazarow
Topic: 45578 Message: 45578

Having seen many "misconstrued" requests for help and subsequent responses in the Group,

I believe that the main issues are that "Newbies" don't always appreciate the complexity of their rigs, the difficulty of remote diagnosis and repair, the parts situation, the need for basic electronics knowledge and test equipment. No one in their right mind would say " I bought a 1957 Chevy on e-bay. It was in an accident, I think, and it doesn't run...can anyone fix it for me?"....but it happens here all of the time..

I think a few procedural items might make things easier on everyone. (Not looking for "volumes" of information) It can be kept short.

All correspondence should have a name and call, or an ex-call, or an indicator of level of interest (ie, CB, non-Ham hobby). Every single message should NAME the RIG in Question..

Perhaps a "read me first" explaining how difficult remote rig repair or solving power/SWR problems, etc are,,,AND what will expected from the requester

Requests for assistance might be accompanied by a short form designed to determine the tube and related experience of the requester, available test equipment, steps already taken, t, and other similar relevant information.

I have also suggested in the past the use of pictures, when it makes sense, to aid with remote diagnoses., especially if taken off-line

I also recommend that if the information is not clearly or accurately presented, people should simply refrain from responding and "move on" after the first or second "go-around" indicates that communications or reality are not pointing toward an amiable "give and take" scenario.

This is a highly technical part of a HOBBY; it's tough to be an "appliance operator" with an old rig, limited parts available, possible modifications, inacurrate or misleading documentation, and so on

My respect and thanks who try to help when they can.

Among my other related experiences, I ran Computer Remote Help Desks in all size companies up to "huge", and that experience,,especially in the early days when all of this stuff was new, and not commonly kept at home, is similar to what our guys face, except worse...

Topic: 45574 Message: 45579

I could be wrong but in the event that Kenny is referring to the 520 verses the 520S then here are some of the differences between those 2 models:

1. The 520S has 160 meters but the 520 does not.

2. The dial on the 520S is different than the 520.

3. RL1 on the GENERATOR Unit in the 520 was removed/replaced with a revised circuit on the 520S GENERATOR Unit.

4. The 520S had the PHONE PATCH IN/OUT sockets on the rear panel but the 520 did not.

5. The 520S has the HET/VFO/CAR sockets plus a 2 pin 13.6VDC socket for the DG-5 digital display but the 520 has none of these

6. The DC to DC converter, DS-1A, was an optional item in the 520S but was standard from the factory in the 520.

7. The 4 position crystal control (FIX) option was located to the right of the meter in the 520 but that switch was moved to an outer ring switch on the LOAD control in the 520S

8. The Meter switch was located on the LOAD control in the 520 but was moved to the right of the meter in the 520S

The TS-520SE is the same transceiver as the TS-520S except for 2 non-supported features:

1. The TS-520SE is designed to operate from 120/240VAC ONLY (the DC-1A DC to DC converter power option is not supported)

2. The HEATER switch was eliminated in the TS-520SE (driver and both final tube filaments were constantly lit as long as either 120VAC or 240VAC (switch selectable) is applied to the TS-520SE and the main power switch is set to ON).

Barry

I did not take anything you said as mocking or sarcastic. I was not offended in any way. I simply did not know how tell you a second time that peaking at a particular level makes no difference. I gave a short bit of fundamentals to help you understand what you are doing this step. Hopefully there will come a time when you will be able to mentally visualize what is on the other end of each knob you are turning and what it is doing, how it does it, why you adjust it a certain way, and what happens if you do not. That will take some time and can be enhanced if you do some self study.

I was trying to tell you because there are so many different approaches to loading that absent a good video if you follow the loading instructions in your manual it is a method that is as good as any and closest to the ideal way to load a Class AB1 final. Only thing better would be if you had a screen grid current meter.

As I stated in my first response to you I can see why most people who read the manual have an immediate question as to what they mean when they say peak the Drive control for maximum meter indication. It begs the question " what maximum?" On what scale? Probably 10 years ago when I bought my first KW hybrid and I read the manual I had the same question. Absent an elmer or this forum I had to dig in and learn what I was doing when I was turning that knob. I had a little easier time as I had 40 years of experience at that time and grew up in the tube era. Before I understood we were just looking at RF voltage swing I probably was hung up on grid current as well as so many seem to be. We grew up with bold cautions never to exceed 3ma or 4ma and make sure you go back and check again after fully loaded. Different transmitter, different class of operation. Apples and oranges.

I did not and do not think you are stupid or ignorant. I have no problem with you questioning what I say or anyone else when you still do not understand or if your knowledge and experience base gives you a different perspective.

Yes talking over the phone can be better than emailing.

(sorry to admins about my posting mishaps not sure what was sent to yall but I kept hitting enter and not tab) a quick reminder of who I am, names Daniel Weed im 28 and new to electronics and radio. I was gifted a ts820s with a bad receiver and after receiving the advice from yall im better off having a club help me before I turn it on again its been sitting on the bench. As im ordering test equipment, so far I have a signal generator combo with a tracer and a vtvm, I got some deoxit to clean some of the connections and after labeling all the plugs I didn't take notice of the pins on the IF board. The plugs that attach to IF 2 and IF 1 leave one pin remaining that isn't plugged into anything im guessing its the pin labeled RIF on IF 1 but I just want to be sure.

Dan Weed
(no call sign yet)

I don't have a call sign because im waiting to get it when I join a local club and since I will be begging for some help on fixing this radio I want to learn a little more about electronics and some of the circuits in it.

Dan,

  I think you just found out how important it is to take notes/pictures prior to removing any
connectors or wires.

With the rig turned bottom up...front panel to your left: the terminal RIF on the IF BOARD is at far RIGHT (or to the rear of the rig), A 3 hole connector with a "clear" wire, middle hole empty, and a "black wire go here...the "clear wire goes to the RIF terminal

The next is a 5 wire connector: colors go from right to left: white...red...green...white w/grey stripe

eire36,

  I agree with Gordon-n6wk....I think you have a fried L-41....also known as the "antenna step up transformer." This is usually marked "1.8" on the RF board. 100 watts is a lot to absorb, and also nearby lightning strikes have also been known to fry them too. The wire that these are wound with is #42awg enameled wire..it's finer that a human hair!

  Don't know where you are...but ...gee...guess what..Gordon-n6wk rewinds them!...but you gotta send him your bad one...contact him through this board.

Also, it is customary here, to sign the end of your posts with your first name and call if any.

Hi all

I am looking for T6 on the RF board of the Kenwood TS-440s. It's listed as a 45.05Mhz Coil - have posted in the 440 Yahoo Group too.

Kenwood Part no is L34-2283-05 but T3 - T7 are all 45.05 MHz coils.

If anyone has one they could sell me i would be most appreciative.

Thanks

Terry,

OK, I ran the same test you did. I connected the generator to pin 4 of the CAR-2 board and set the output for 300mV rms at 8830.70. I am using my scope and doing the math to convert from peak-peak to rms.

At D7 anode I increased the Car Pot level to 30mV rms. This occurred at about 2-1/2 position.

I then moved to the anode of D8 and swept from 8830.0 to 8840.0 At those two frequencies the signal is virtually non-existent. The peak occurs at 8830.30 and is approximately 18mV. It is hard to tell exactly because the signal is jumping around on my scope.

Either side of that frequency the signal drops off fast. For example, if I change the frequency to 8830.32 of 8830.28, the signal drops about 16mV.

I guess this pretty much confirms the filter is bad. I can still remove it from the board and sweep it with 600 ohm terminations but I don't think it will change anything.

Do you think at this point I should just get another CW filter and try it?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Ok dinner is over and grand kids gone and house quiet. I need a beer!

Here is what I did to sweep the CW filter:

1. Removed the Carrier Osc metal cover 2 screws and exposed CAR-2 board
2. Removed small screw in center of the board.
3. Gently wiggled and pulled on the 10 pin Molex connector and removed the board
4. Connected RF Sig Gen output cable to pins 4 and 3 . Hot lead to 4 and shield to 3 or ground
5. Powered rig on in CW mode. Heaters and SG switch off. Drive control at 1200. VFO at 14.2mhz, and CAR Level pot full CCW.
6. Connected RF millivolt meter to IF board TP-5 and adjusted RF Sig gen output for 300mv rms @ 8830.70.
7. Connected RF millivolt meter to Diode D7 at input to the CW filter and flipped rig to Send and increased Car Level Pot for approx 30 mv input. Car Pot level was at position "2" for 30 mv carrier level. .
8. Moved RF millivolt meter to Diode D8 and swept the RF sig gen from 8800 to 9000. Found peak in RF voltage at approx 15 mv at 8830.689.

So the Fc of my filter is very close to 8830.70 and the attenuation closely matches what is listed on the TX Level Diagram.

Suggest you do not use much more than 30mv rms or 85 mv p-p input at Diode D7.

Ray

Apparently I am wrong about in situ sweeping of the CW filter by injecting inside Anode of D7 and measuring inside Anode of D8 and using no series source resistor at the input and no shunt load resistor at the output.

As I previously mentioned using these resistors is standard practice for testing crystal lattice filters on the bench. If you know the values of the internal input and output capacitors (not likely unless you are homebrewing the filters) there are formulas for calculating the resistance values absent knowing the factory impedance values. I have had good success using two resistor divider at input and output or using a pot to ground on each end and connecting the sig gen and rf measuring device to the wipers of the pots. Can then adjust the pots to get the optimum signal levels.

I had hoped this short cut method would show if the Fc had radically shifted and/or if there was an inordinate amount of signal attenuation.

I performed your test method on my TS820 CW filter early this am and the peak RF voltage occurred at 8830.52 and not 8830.70. By those results we would say my filter is bad and I know it is not as I get full CW output with it and my CA-2 carrier frequency is spot on 8830.7.

A couple of other in situ methods come to mind:

1. Rig powered off
2. Apply 12vdc from a dc bench supply or couple of lantern batteries to Molex Conn IF-2 Pins 4 and 5. This will turn on D7 and D8 filter switching diodes.
3. Inject test Rf signal at Cathode of D7 and measure the RF output at cathode of D8.

4. This method inserts the source and load resistance that the filter sees in operation.

OR

1. Rig powered on
2. Disable CA-2 8830.7 input to IF board
3. Inject test RF signal at TP-5
4. Measure RF output at cathode of D8.

I have a pretty full plate today so will think about this and perhaps after dinner tonite can try one or both of these above methods.

Ray

Much better got it all this time.

Yes the diode barrier voltages will vary as the dc supply and line voltage will also vary. As long at the diodes are the original silicon diodes then 0.6vdc to 0.7vdc is typical. You are looking for gross differences between what I read. I looked at your readings and I agree the diodes are fine and the switching voltage supply to them is there.

Yes for most accurate sweep should terminate filter input and output in its characteristic impedance, but for this test what you have should be OK as we are only interested in relative rf voltages. I dont know what the input/output impedance of this filter is. Most of the KW filters have impedances that range from 300 ohms to 2k ohms that I have seen. You could experiment and repeat test with resistor divider on each end.

When I sweep a KW filter out of the rig on the bench I look at service manual for the input/output impedance. I then make a 2 resistor divider at each side of the filter. For example if the filter Z is 600 ohms I will place a 600 ohm resistor in series with the filter input and a 50 ohm resistor in shunt to ground. I connect the sig gen to the free end of the 600 ohm series resistor. Do same at output and connect the O-scope or RF millivolt meter to the free end of the 600 ohm resistor.

You can see that if your CW TX carrier frequency is 8830.7 as it should be then it will be outside the -6dB bandpass of the filter if the measured FC is 8830.3.

I will try to get time tomorrow and sweep my filter in place using same method you employed for comparison.

What you know for sure is :
1. D7/D8 are being biased on in CW mode.
2. With .047 cap bridging the filter you get full RF output in CW mode
3. With cap removed no RF output

Sure looks like filter is the culprit.

You are doing some good work here. Absent test gear, knowing how to use it, ability to read a schematic, and some familiarization with the board layouts this is a challenging task for any hybrid owner.

I will get back with my sweep results.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

Let me try again. The unreadable post has been happening a lot since Yahoo went to this new format last month.

With the .047 cap on the anodes of D7 and D8 I am able to obtain full output in CW mode. Also, both diodes are forward biased in CW Send mode as I see approximately .6 volts drop across them in Pos C. The voltages are about .1 volt lower than what you are showing.

Do you know the impedance of the crystal filters in the TS-820? This is the signal source I have to use to test with:
http://www.oocities.org/hagtronics/source/index.html
It has a 50 ohm output. I also have a HP 3314A I could use but it is also 50 ohms out.

With the signal source set to -1 dB out and in and out connections at the anodes of D7 and D8, I get these are the readings I get:
8.8300 - -46.9 dB
8.8301 - -33.3 dB
8.8302 - -19.5 dB
8.8303 - -14.4 dB
8.8304 - -17.5 dB
8.8305 - -26.4 dB
8.8306 - -28-5 dB
8.8307 - -42.5 dB
8.8308 - -49.5 dB
8.8309 - -49.7 dB
8.8310 - -50.0 dB

The filter FC appears to be at 8.8303. My scope with 1 meg load agrees with this as I see the peak on it at the same frequency. I don't know how much the 50 ohm generator and power meter loads are affecting the filter.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray that is because you have the test cap on the Cathode sides of D7 and D8. Move the cap to the Anode sides of each and the plug to Pos C. Now you are checking the diodes as well.

This test proves that you have sufficient RF carrier level from the BM available at the Cathode of D7 to produce full output in CW.

Problem is if jumpering the filter works then which is bad? The CW filter or one or both diodes or the bias supply to the diodes?

I would focus all my efforts with the plug in Pos C to simplify reading taking.

In Pos C you need to ensure that each diode is forward biased.

D7 Cathode = 2.85vdc
D7 Anode = 2.25vdc

D8 Cathode = 9.8vdc
D8 Anode = 9.2vdc

Pretty sure you have already done this and confirmed you have diode supply voltage and good diodes so that just the filter.

Do you have an RF sig generator? If you do you can sweep the filter. It will tell you couple of things.
1. Where is Fc at (center frequency)
2. What is its attenuation

Doesnt have to be a sophisticated or accurate RF sig gen.

Can set it at around 8.0 mhz as measured by your Simpson Freq counter and set the rf output level to approx 200mv as measured by your O-scope.

Connect the output from RF sig gen to Anode of D7 and your O-scope at Anode of D8 (rig power is off) and slowly raise the frequency and see where the peak RF output voltage occurs at. Should be close to 8830.7khz. This assumes your sig gen output voltage doesnt vary greatly for small change in frequency. If it does you would need two ways to measure RF so you could ride the sig gen output to keep it constant.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry, with a .047 capacitor across the CW filter, I get full output in CW mode regardless of what position the IF2 connector is in.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

These are the readings taken with IF2 connector in all three positions (P-P values):
Position A: D7 cathode: 800mV CW, 800 mV FSK --- D8 cathode: 600mV CW, 400mV FSK
Position B: D7 cathode: 600mV CW, 800 mV FSK --- D8 cathode: 44mV CW, 400 mV FSK
Position C: D7 cathode: 260mV CW, 800 mv FSK --- D8 cathode: 40mV CW, 400 mV FSK
All readings were taken with my scope with the probe in the 10X position to prevent loading of the circuit.

These are the DC readings for D7 and D8 in all three positions (RMS values):
Position A: CW - D7 anode: -3.6V, cathode: 2.0V -- D8 anode: 0V, cathode: 9.0V
Position A: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode 8.5V
Position B: CW - D7 anode: 2.8V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.7V
Position B: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode: 8.5V
Position C: CW - D7 anode: 2.8V, cathode: 2.2V -- D8 anode: 9.3V, cathode: 8.6V
Position C: FSK - D7 anode: 2.7V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.6V

The only position I get output in CW mode is when the connector is in position A.

The CW filter is a TRIO YG-88C and I have re-soldered all connections on the filter.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

I meant Cathode voltages but I think you get the idea. Measure the Anode and Cathode to ensure both diodes are being switched on. Should see approx 0.65 vdc drop across D7 and D8 as they are silicon diodes.

Not likely bad but if you need to replace I offer the following:

Should you need a diode do not use a NTE 177 sub. These are 1S1587 fast switching diodes with a fast reverse recovery time of approx 2 ns so I would not use a general purpose silicon diode as NTE sub guide suggests. Can use a NTE 519, but it has a recovery time of approx 70 ns.

I think a 1N914 or 1N4148 would be better choice at 4ns..These are still pretty commonly available.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK I forgot to give you the Anode voltages of D7 and D8 but you can just subtract approx 0.65vdc for the turn on voltage.

280mv P-P is high by my measurements, but if you read close to same in FSK-T then call it good. Certainly better than be too low.

6 mv P-P at output in CW-T is definitely a problem. As I said you can jumper the filter with a .047uf cap and see if you get CW Tx.

Is this the factory YG-88C filter?

I believe it has center frequency of 8830.7 mhz.and bandwidth of 500hz at -6dB.
I have never swept one.

It would not seem likely that you would have bad solder connections if the filter is working in FSK mode. Are you 100% certain you are not using the SSB filter in FSK mode?

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

My voltages at D7 and D8 are virtually identical to yours. I had previously measured the levels at D7 and D8. I measured 280mV P-P where C14 connects to the CW filter and only 6mV P-P out of the filter. But that was before I changed the cable to position A. I will have to move the cable back to C and re-measure tomorrow. I will also pull the IF board out and resolder the CW crystal filter connections. It may be bad solder connections as you suggest.

I just made my first contact in 17 years on 7.020 with W5TZC about 30 mins ago. He gave me a 579 which is pretty good considering my antenna is only 8 feet off the ground. I also still have to address why they final isn't tuning properly on 40 meters. It tuned max power with plate knob pointer sitting on the 5 of 3.5. It dips at 14 on 20 meters.

If I can get the CW filter issue worked out I will go through a complete tuneup of the radio following the service manual procedures.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

It is easy to test CW filter switching diodes D7 and D8. I thought you already did this and reported good?

As previously noted my plug is in C all the way toward the front panel.

Conn IF-2 pins 4 and 5 have approx 12.9vdc on them in Rx and Tx for CW-R, CW-T, FSK-R, and FSK-T.

The cathode of D7 is:
CW-R and FSK-R = 2.90vdc
CW-T and FSK- T = 2.90vdc

The cathode of D8 is : (Note: When you connect voltmeter back ground noise will drop significantly).
CW-R and FSK-R = 10.0vdc
CW-T and FSK-T = 9.80vdc

The reading will be different as the diodes are biased to different current levels. You can see the difference in the supply resistors for each diode.

I have never been able to measure TX level diagram RF voltages accurately using a 1X scope probe. It will pull your ALC indication down from FSD (40 over) to approx 25 over.

You should be able to measure the 8.830mhz TIF signal level at the input and output of the CW Xtal filter. I thought we did this a long time ago?

It is normal for the filters to have an insertion loss. Should have a minimum of approx 25mv rms at D7 input and minimum of approx 19mv rms at D8 output.

Here are my RF level measurements at D7 and D8:

Test conditons: 14.175mhz, Heater on , SG switch off, CW mode, Drive control peaked, Car Pot at 2.5 (for full scale ALC deflection or 40 over)

Boonton 92E (using 10x scope probe very close to same levels)
D7 = 58mv
D8 = 25mv

You can jumper across your CW filter with a couple of mini-grabber test leads with a 0.047uf capacitor in series.

Could have good switching diodes and good filter but bad solder connections at the filter?

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I have made a discovery that will probably tell us where the actual problem is. I was googling how to replace CW filter and found this link:
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2

So I downloaded the operators manual and looked at page 34. Kenwood is perfectly clear about this. If the plug is in position A, the CW filter is bypassed.

I put the plug in position A and can tune to full power out in CW mode. If I place the plug in position B or C I get no power out when in CW mode.

Does this indicate a bad CW filter? The filter works fine in receive mode. The only thing I have noticed is that if I switch from USB to CW the signal drops 1 S-unit when peaked for max signal in both modes.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

At this point I am using my scope with 1 meg input. If is become suspicious of the reading I switch the 10X on and take the reading that way.

An immediate problem I see is I only have 10mV P-P at the drain of Q1 in FSK mode and 0 output in CW mode. The diagram says there should be 250 mV rms there. If I pull the CW filter out of the radio, how does the CW transmit work? Does the signal then go through the

USB filter or do I need to install a jumper where the CW filter was?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Yes they are RMS.

I take them at around 14.175 to 14.200 mhz with the Car Level pot advanced to the point that with the Drive Control adjusted for a peak in ALC indication at panel meter full scale deflection. Then switch to CW mode and load to approx 100 watts out and turn off SG switch. Leave Car Level and Drive control alone.

Measured values will vary depending on what test instrument you are using, length of any test jumper leads used to access the test points, line voltage.

For example 8.830mhz TIF output at the IF board and input at the RF board is shown as 0.038v. This is 38.0 mv rms rf volts or 38 x 2.828 = 107 mv P-P. So if you have approx 100mv P-P TIF you are good.

Output of the TX Mixer is 1.4v rms or 4.0v P-P. This RF drive level is now 14.175 mhz.

If you plan on doing a lot of this work suggest you invest in a RF Millivolt meter. I use a Boonton 92E. I find it loads the circuits less and just easier and faster to use.

Of coures once you get to the 1.4 volts at output of the TX Mixer the old fashioned RF probe and VTVM works great. Just have to use multi-diode probe at plate of Driver tube and control grids of the Finals. I used a Heath 309C and PK-3 probes and a IM-18 VTVM for years and still have them for fall back.

Thanks Terry. I have been talking to you since you have been helping. I don't know what made me put Dave on the last message (old age maybe).

I decided to start over from the beginning and go stage by stage this afternoon. This is what I did:
(All measurements taken with Send switch operated and Mode switch in CW position. Also, the measurements are the same in both CW and FSK modes.)

I suspected D1 or L1 was bad on the CAR-II board was bad but that is not the case. I have 720mV on CA2 leaving the CAR-II board in both CW and FSK send modes. I also have 720mV P-P on CA2 (IF5-13) on the IF board. I have 100mV P-P at the coax that connects to C92 on the IF board. On the other end of that coax where it connects to the top of T4 on the IF board I also have 100mV P-P. I would have thought the signal out of Q18 would have been stronger

but maybe not.

I have 340mV at the junction of the cathode of D7 and C14 on the IF board. I have 280mV on the side of C14 where it feeds the CW filter. The signal going into the filter measures 8.830755 MHz. I only have 6mV P-P coming out of the crystal filter. Is the crystal filter used for transmit?

I connected the antenna to the radio and 20 meters is open. Tuning in CW signals in USB mode and switching to CW mode drops the signal by about 1 S-Unit when the signal is peaked for max signal in both modes.

Where do I go from here?

Ray AB7HE

Although to be fair, a 1957 Chevy (or any car, up to the late 80s) is about as technical as a hammer and can generally be got started if you can confirm the presence of roughly the right amounts of fuel, electricity and compression!

As they say, "You can have a toolbox and not have an old Landrover, but you can't have an old Landrover and not have a toolbox". In the case of our beloved old boatanchors, the toolbox is more mental than physical (although a perspex knitting needle with the end filed to a screwdriver tip is invaluable for that neutralising cap).

Ray:

I obviously did not witness your test so can only go by what you report back.
I dont understand why your signal is jumping around on the scope. Dont know how you are triggering the sweep? Should be a stable waveform display.

However with 30 mv input and 18 mv output that agrees with attenuation you should expect.

My test revealed that my filter was very close to 8830.7 khz Fc.

Any of these filter sweeps depend on the accuracy of the test gear you have. Ideally you would need a Sweep generator with accurate KW markers, or a Spectrum analyzer with a tracking generator, or a 2 port VNA (make some nice USB ones today). Absent these classic test gear then you have to use the old fashioned manual method you just employed. It has been done this way for years and plotted on graph paper (before PC and Excel!) .

However results are no better than the accuracy of your RF sig gen output frequency.

One other thing you could try is to key the rig with heater and SG switch on into dummy load and see if you now get out good RF output with your test 8830.30 injected at pin 4 in lieu the rigs carrier oscillator. You know with the 8830.7 applied by the CAR-2 board it doesnt produce any RF output in CW mode so if your filter Fc has shifted to 8830.3 you should see good RF output power by injecting that carrier oscillator frequency. Actual transmit RF output freq will be off a little but not of concern.

Other wise you can remove the filter and sweep in on bench terminated with the 600 ohm source resistor and the 600 load resistor.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

OK, I ran the same test you did. I connected the generator to pin 4 of the CAR-2 board and set the output for 300mV rms at 8830.70. I am using my scope and doing the math to convert from peak-peak to rms.

At D7 anode I increased the Car Pot level to 30mV rms. This occurred at about 2-1/2 position.

I then moved to the anode of D8 and swept from 8830.0 to 8840.0 At those two frequencies the signal is virtually non-existent. The peak occurs at 8830.30 and is approximately 18mV. It is hard to tell exactly because the signal is jumping around on my scope.

Either side of that frequency the signal drops off fast. For example, if I change the frequency to 8830.32 of 8830.28, the signal drops about 16mV.

I guess this pretty much confirms the filter is bad. I can still remove it from the board and sweep it with 600 ohm terminations but I don't think it will change anything.

Do you think at this point I should just get another CW filter and try it?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray:

Ok dinner is over and grand kids gone and house quiet. I need a beer!

Here is what I did to sweep the CW filter:

1. Removed the Carrier Osc metal cover 2 screws and exposed CAR-2 board
2. Removed small screw in center of the board.
3. Gently wiggled and pulled on the 10 pin Molex connector and removed the board
4. Connected RF Sig Gen output cable to pins 4 and 3 . Hot lead to 4 and shield to 3 or ground
5. Powered rig on in CW mode. Heaters and SG switch off. Drive control at 1200. VFO at 14.2mhz, and CAR Level pot full CCW.
6. Connected RF millivolt meter to IF board TP-5 and adjusted RF Sig gen output for 300mv rms @ 8830.70.
7. Connected RF millivolt meter to Diode D7 at input to the CW filter and flipped rig to Send and increased Car Level Pot for approx 30 mv input. Car Pot level was at position "2" for 30 mv carrier level. .
8. Moved RF millivolt meter to Diode D8 and swept the RF sig gen from 8800 to 9000. Found peak in RF voltage at approx 15 mv at 8830.689.

So the Fc of my filter is very close to 8830.70 and the attenuation closely matches what is listed on the TX Level Diagram.

Suggest you do not use much more than 30mv rms or 85 mv p-p input at Diode D7.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Ray

Apparently I am wrong about in situ sweeping of the CW filter by injecting inside Anode of D7 and measuring inside Anode of D8 and using no series source resistor at the input and no shunt load resistor at the output.

As I previously mentioned using these resistors is standard practice for testing crystal lattice filters on the bench. If you know the values of the internal input and output capacitors (not likely unless you are homebrewing the filters) there are formulas for calculating the resistance values absent knowing the factory impedance values. I have had good success using two resistor divider at input and output or using a pot to ground on each end and connecting the sig gen and rf measuring device to the wipers of the pots. Can then adjust the pots to get the optimum signal levels.

I had hoped this short cut method would show if the Fc had radically shifted and/or if there was an inordinate amount of signal attenuation.

I performed your test method on my TS820 CW filter early this am and the peak RF voltage occurred at 8830.52 and not 8830.70. By those results we would say my filter is bad and I know it is not as I get full CW output with it and my CA-2 carrier frequency is spot on 8830.7.

A couple of other in situ methods come to mind:

1. Rig powered off
2. Apply 12vdc from a dc bench supply or couple of lantern batteries to Molex Conn IF-2 Pins 4 and 5. This will turn on D7 and D8 filter switching diodes.
3. Inject test Rf signal at Cathode of D7 and measure the RF output at cathode of D8.

4. This method inserts the source and load resistance that the filter sees in operation.

OR

1. Rig powered on
2. Disable CA-2 8830.7 input to IF board
3. Inject test RF signal at TP-5
4. Measure RF output at cathode of D8.

I have a pretty full plate today so will think about this and perhaps after dinner tonite can try one or both of these above methods.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Ray

Much better got it all this time.

Yes the diode barrier voltages will vary as the dc supply and line voltage will also vary. As long at the diodes are the original silicon diodes then 0.6vdc to 0.7vdc is typical. You are looking for gross differences between what I read. I looked at your readings and I agree the diodes are fine and the switching voltage supply to them is there.

Yes for most accurate sweep should terminate filter input and output in its characteristic impedance, but for this test what you have should be OK as we are only interested in relative rf voltages. I dont know what the input/output impedance of this filter is. Most of the KW filters have impedances that range from 300 ohms to 2k ohms that I have seen. You could experiment and repeat test with resistor divider on each end.

When I sweep a KW filter out of the rig on the bench I look at service manual for the input/output impedance. I then make a 2 resistor divider at each side of the filter. For example if the filter Z is 600 ohms I will place a 600 ohm resistor in series with the filter input and a 50 ohm resistor in shunt to ground. I connect the sig gen to the free end of the 600 ohm series resistor. Do same at output and connect the O-scope or RF millivolt meter to the free end of the 600 ohm resistor.

You can see that if your CW TX carrier frequency is 8830.7 as it should be then it will be outside the -6dB bandpass of the filter if the measured FC is 8830.3.

I will try to get time tomorrow and sweep my filter in place using same method you employed for comparison.

What you know for sure is :
1. D7/D8 are being biased on in CW mode.
2. With .047 cap bridging the filter you get full RF output in CW mode
3. With cap removed no RF output

Sure looks like filter is the culprit.

You are doing some good work here. Absent test gear, knowing how to use it, ability to read a schematic, and some familiarization with the board layouts this is a challenging task for any hybrid owner.

I will get back with my sweep results.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

Let me try again. The unreadable post has been happening a lot since Yahoo went to this new format last month.

With the .047 cap on the anodes of D7 and D8 I am able to obtain full output in CW mode. Also, both diodes are forward biased in CW Send mode as I see approximately .6 volts drop across them in Pos C. The voltages are about .1 volt lower than what you are showing.

Do you know the impedance of the crystal filters in the TS-820? This is the signal source I have to use to test with:
http://www.oocities.org/hagtronics/source/index.html
It has a 50 ohm output. I also have a HP 3314A I could use but it is also 50 ohms out.

With the signal source set to -1 dB out and in and out connections at the anodes of D7 and D8, I get these are the readings I get:
8.8300 - -46.9 dB
8.8301 - -33.3 dB
8.8302 - -19.5 dB
8.8303 - -14.4 dB
8.8304 - -17.5 dB
8.8305 - -26.4 dB
8.8306 - -28-5 dB
8.8307 - -42.5 dB
8.8308 - -49.5 dB
8.8309 - -49.7 dB
8.8310 - -50.0 dB

The filter FC appears to be at 8.8303. My scope with 1 meg load agrees with this as I see the peak on it at the same frequency. I don't know how much the 50 ohm generator and power meter loads are affecting the filter.

8.8306 - -28-5 dB
8.8307 - -42.5 dB
8.8308 - -49.5 dB
8.8309 - -49.7 dB
8.8310 - -50.0 dB

The filter FC appears to be at 8.8303. My scope with 1 meg load agrees with this as I see the peak on it at the same frequency. I don't know how much the 50 ohm generator and power meter loads are affecting the filter.

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Ray that is because you have the test cap on the Cathode sides of D7 and D8. Move the cap to the Anode sides of each and the plug to Pos C. Now you are checking the diodes as well.

This test proves that you have sufficient RF carrier level from the BM available at the Cathode of D7 to produce full output in CW.

Problem is if jumpering the filter works then which is bad? The CW filter or one or both diodes or the bias supply to the diodes?

I would focus all my efforts with the plug in Pos C to simplify reading taking.

In Pos C you need to ensure that each diode is forward biased.

D7 Cathode = 2.85vdc
D7 Anode = 2.25vdc

D8 Cathode = 9.8vdc
D8 Anode = 9.2vdc

Pretty sure you have already done this and confirmed you have diode supply voltage and good diodes so that just the filter.

Do you have an RF sig generator? If you do you can sweep the filter. It will tell you couple of things.
1. Where is Fc at (center frequency)
2. What is its attenuation

Doesnt have to be a sophisticated or accurate RF sig gen.

Can set it at around 8.0 mhz as measured by your Simpson Freq counter and set the rf output level to approx 200mv as measured by your O-scope.

Connect the output from RF sig gen to Anode of D7 and your O-scope at Anode of D8 (rig power is off) and slowly raise the frequency and see where the peak RF output voltage occurs at. Should be close to 8830.7khz. This assumes your sig gen output voltage doesnt vary greatly for small change in frequency. If it does you would need two ways to measure RF so you could ride the sig gen output to keep it constant.

Terry, with a .047 capacitor across the CW filter, I get full output in CW mode regardless of what position the IF2 connector is in.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

These are the readings taken with IF2 connector in all three positions (P-P values):
Position A: D7 cathode: 800mV CW, 800 mV FSK --- D8 cathode: 600mV CW, 400mV FSK
Position B: D7 cathode: 600mV CW, 800 mV FSK --- D8 cathode: 44mV CW, 400 mV FSK
Position C: D7 cathode: 260mV CW, 800 mv FSK --- D8 cathode: 40mV CW, 400 mV FSK
All readings were taken with my scope with the probe in the 10X position to prevent loading of the circuit.

These are the DC readings for D7 and D8 in all three positions (RMS values):
Position A: CW - D7 anode: -3.6V, cathode: 2.0V -- D8 anode: 0V, cathode: 9.0V
Position A: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode 8.5V
Position B: CW - D7 anode: 2.8V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.7V
Position B: FSK - D7 anode: 0V, cathode: 2.0V -- D8 anode: 0V, cathode: 8.5V
Position C: CW - D7 anode: 2.8V, cathode: 2.2V -- D8 anode: 9.3V, cathode: 8.6V
Position C: FSK - D7 anode: 2.7V, cathode: 2.1V -- D8 anode: 9.3V, cathode: 8.6V

The only position I get output in CW mode is when the connector is in position A.

The CW filter is a TRIO YG-88C and I have re-soldered all connections on the filter.

I meant Cathode voltages but I think you get the idea. Measure the Anode and Cathode to ensure both diodes are being switched on. Should see approx 0.65 vdc drop across D7 and D8 as they are silicon diodes.

Not likely bad but if you need to replace I offer the following:

Should you need a diode do not use a NTE 177 sub. These are 1S1587 fast switching diodes with a fast reverse recovery time of approx 2 ns so I would not use a general purpose silicon diode as NTE sub guide suggests. Can use a NTE 519, but it has a recovery time of approx 70 ns.

I think a 1N914 or 1N4148 would be better choice at 4ns..These are still pretty commonly available.

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

OK I forgot to give you the Anode voltages of D7 and D8 but you can just subtract approx 0.65vdc for the turn on voltage.

280mv P-P is high by my measurements, but if you read close to same in FSK-T then call it good. Certainly better than be too low.

6 mv P-P at output in CW-T is definitely a problem. As I said you can jumper the filter with a .047uf cap and see if you get CW Tx.

Is this the factory YG-88C filter?

I believe it has center frequency of 8830.7 mhz.and bandwidth of 500hz at -6dB.
I have never swept one.

It would not seem likely that you would have bad solder connections if the filter is working in FSK mode. Are you 100% certain you are not using the SSB filter in FSK mode?

Terry K9TW

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

My voltages at D7 and D8 are virtually identical to yours. I had previously measured the levels at D7 and D8. I measured 280mV P-P where C14 connects to the CW filter and only 6mV P-P out of the filter. But that was before I changed the cable to position A. I will have to move the cable back to C and re-measure tomorrow. I will also pull the IF board out and resolder the CW crystal filter connections. It may be bad solder connections as you suggest.

I just made my first contact in 17 years on 7.020 with W5TZC about 30 mins ago. He gave me a 579 which is pretty good considering my antenna is only 8 feet off the ground. I also

still have to address why they final isn't tuning properly on 40 meters. It tuned max power with plate knob pointer sitting on the 5 of 3.5. It dips at 14 on 20 meters.

If I can get the CW filter issue worked out I will go through a complete tuneup of the radio following the service manual procedures.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

It is easy to test CW filter switching diodes D7 and D8. I thought you already did this and reported good?

As previously noted my plug is in C all the way toward the front panel.

Conn IF-2 pins 4 and 5 have approx 12.9vdc on them in Rx and Tx for CW-R, CW-T, FSK-R, and FSK-T.

The cathode of D7 is:
CW-R and FSK-R = 2.90vdc
CW-T and FSK- T = 2.90vdc

The cathode of D8 is : (Note: When you connect voltmeter back ground noise will drop significantly).
CW-R and FSK-R = 10.0vdc
CW-T and FSK-T = 9.80vdc

The reading will be different as the diodes are biased to different current levels. You can see the difference in the supply resistors for each diode.

I have never been able to measure TX level diagram RF voltages accurately using a 1X scope probe. It will pull your ALC indication down from FSD (40 over) to approx 25 over.

You should be able to measure the 8.830mhz TIF signal level at the input and output of the CW Xtal filter. I thought we did this a long time ago?

It is normal for the filters to have an insertion loss. Should have a minimum of approx 25mv rms at D7 input and minimum of approx 19mv rms at D8 output.

Here are my RF level measurements at D7 and D8:

Test conditons: 14.175mhz, Heater on , SG switch off, CW mode, Drive control peaked, Car Pot at 2.5 (for full scale ALC deflection or 40 over)

Boonton 92E (using 10x scope probe very close to same levels)
D7 = 58mv
D8 = 25mv

You can jumper across your CW filter with a couple of mini-grabber test leads with a 0.047uf capacitor in series.

Could have good switching diodes and good filter but bad solder connections at the filter?

Terry K9TW.

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

Terry,

I have made a discovery that will probably tell us where the actual problem is. I was googling how to replace CW filter and found this link:
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2
http://www.eham.net/ehamforum/smf/index.php?topic=4925.0;wap2

So I downloaded the operators manual and looked at page 34. Kenwood is perfectly clear about this. If the plug is in position A, the CW filter is bypassed.

I put the plug in position A and can tune to full power out in CW mode. If I place the plug in position B or C I get no power out when in CW mode.

Does this indicate a bad CW filter? The filter works fine in receive mode. The only thing I have noticed is that if I switch from USB to CW the signal drops 1 S-unit when peaked for max signal in both modes.

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <rcbuckiii@...> wrote:

Terry,

At this point I am using my scope with 1 meg input. If is become suspicious of the reading I switch the 10X on and take the reading that way.

An immediate problem I see is I only have 10mV P-P at the drain of Q1 in FSK mode and 0 output in CW mode. The diagram says there should be 250 mV rms there. If I pull the CW filter out of the radio, how does the CW transmit work? Does the signal then go through the USB filter or do I need to install a jumper where the CW filter was?

Ray AB7HE

---In ts-520_820_530_830@yahoogroups.com, <wagstw46@...> wrote:

Yes they are RMS.

I take them at around 14.175 to 14.200 mhz with the Car Level pot advanced to the point that with the Drive Control adjusted for a peak in ALC indication at panel meter full scale deflection. Then switch to CW mode and load to approx 100 watts out and turn off SG switch. Leave Car Level and Drive control alone.

Measured values will vary depending on what test instrument you are using, length of any test jumper leads used to access the test points, line voltage.

For example 8.830mhz TIF output at the IF board and input at the RF board is shown as 0.038v. This is 38.0 mv rms rf volts or 38 x 2.828 = 107 mv P-P. So if you have approx 100mv P-P TIF you are good.

Output of the TX Mixer is 1.4v rms or 4.0v P-P. This RF drive level is now 14.175 mhz.

If you plan on doing a lot of this work suggest you invest in a RF Millivolt meter. I use a Boonton 92E. I find it loads the circuits less and just easier and faster to use.

Of coures once you get to the 1.4 volts at output of the TX Mixer the old fashioned RF probe and VTVM works great. Just have to use multi-diode probe at plate of Driver tube and control grids of the Finals. I used a Heath 309C and PK-3 probes and a IM-18 VTVM for years and still have them for fall back.

Glen:

Thanks for the compliment. Please accept what I am about to say in the spirit that it is given. I am trying to help you and not quite sure where to begin.

1. I assume you have some form of wire dipole that you are multi-banding thus the need for the Tuner? That is OK but when learning to load a KW hybrid I recommend you place the Tuner in bypass and learn to load into a dummy load. Using the Tuners watt meter is fine for that. Worry about learning how to adjust the Tuner when feeding an antenna after you have mastered loading in to a dummy load.

2. Your procedure seems needlessly complex and convoluted. Frankly I have no idea what you are doing. Wish I could observe it and give you some feedback.

3. I repeat you did not "miss something in the SSB tune-up". There is NO SSB tune up. If you literally follow Step 4.3 Transmission procedure you are loading or tuning the radio in CW mode.

4. There is no correlation between your Tuner wattmeter and the rigs RF relative power meter indications. I suppose you could load to 100 watts out as indicated by your Tuner wattmeter and then adjust your RF meter sensitivity pot for a full scale reading or pick any level on the meter scale and record that value and then always come back to that point. Making sure your Tuner wattmeter and rigs RF relative power meter match has nothing to do with preventing "over powering" the radio. If you mean by "overpowering" exceeding the 6146 final tube plate dissipation the way that you ensure you do not do that is to avoid long off resonance key down time and do not exceed a maximum of 265ma of plate current in the IP position of the meter. If you are using the Tuner wattmeter to load with (a very good idea) then you will want to leave your panel meter in the IP position. In this way when you load to approx 100 watts out you can see at what plate current that occurs at. On most TS830 rigs with good tubes and good alignment that will occur at approx 200ma to 225ma. You can load to around 250ma with no ill effects, but most fellows limit the plate current to approx 225ma (actually is cathode current which includes screen grid current). So I repeat there is no reason to make any comparisons between the Tuner wattmeter and rigs RF relative power readings. Apples and oranges.

5. In your Step 1 you say you set the CAR level pot at around 6 to 8 and obtain 1 watt output on your Tuner wattmeter. I assume this is adjusting the Drive level in TUNE mode? If it is, then your rig has some issues. At 14.200 mhz you should be able to peak the Drive control to obtain full scale ALC deflection at approx #4 on the CAR pot and should see something on the order of 15 to 17 watts out into the dummy load. Any less than this and you likely have Driver tube issues and/or poor coil pack alignment. Both easy fixes.

6. Your Step 2 makes no sense to me. When reducing the CAR level pot (CCW rotation) the output power indicated on your Tuner wattmeter should fall and not increase.

I cant comment any further on the remainder of your procedure as I am not sure what you are doing and why.

What you need to do is:

1. Peak the Drive control in Tune Mode. Should be close to 1200 at mid VFO range. You can pick any level of ALC indication that you like for this ie middle of black printed scale, far right end of black printed scale, or meter full scale. With good 830 should take no more Car level than approx # 4 on 20 meters. It will vary on each band, but typically should never have to run more than 1200 position.

2. Dip the Plate current in Tune Mode. Do this with the Plate Load cap full CCW (plates fully meshed). You will see something on order of 40 to 50 ma dip. You do this so that when you next move on to CW mode to complete the loading that you are not far off resonance and would have very heavy plate current when you key the rig.

3. You now go to CW mode and leave the meter in IP position. You flip to Send and alternately adjust the Plate Tune and Plate Load controls for a maximum RF output on your Tuner wattmeter. It should be approx 100 watts and IP should read approx 200 to 225 ma.

You are done loading in CW Mode. It cannot get any simpler than this. Three simple steps in no more than 10 seconds or so total key down time.

You now place a code key in the key jack and key the rig and adjust the CAR pot for any level of output power that you want to operate at. Make no other adjustments.

Once you master this then you can learn how to use a small amount of RF drive to adjust the Tuner caps and inductor so your antenna system presents a 50 ohm load to the rig input of the Tuner. You cannot change what the antenna system looks like to the antenna input of the Tuner. You are not "sharply" tuning the antenna with your Tuner. You are taking whatever load impedance that the feed line presents (combination of resistance and reactance) and converting it to 50 ohm resistive load that your rig likes to see. This is why "Trans-Match" is a better name than Tuner. Too complex to go in much detail here.

Terry K9TW

Thanks for the tutorial. Very helpful.
I missed something in the SSB tune-up.

Am using an Antenna Tuner with calibrated Power Meters,
which work with the Knwd 830 "RF" meter relative readings.
That is a double-check against accidently overpowering.

On the Knwd 830, Currently, when changing bands,
1) I set the "Carrier" to the CW #6 or #8.
which produces maybe a 1 W Power Forward at the Antenna Tuner.
2) I begin adjusting Load / Plate / Drive, watching the "IP" and the Tuner Pwr.
I adjust the "Carrier" CCW towards #5 , then #4,
which gradually increases the Power Forward reading in the Antenna Tuner.
3) Back and forth a few times, to get 100 mA "IP" and 25 W Power Forward.

This allows me to sharply tune the antenna.
4) Lastly, I typically I back off towards 5 W Power Forward.

Other than the trusty HW8,
my former experience was with an ARC-5 running pair of 807 at 205 W.
Careful drive and tuning was required else the 807's would turn yellow !

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

G'day,

Turn heaters on and allow a few minutes for the tubes to warm up and get to operating stage.

Turn mode switch to tune and a dummy load and external watt meter connected.

place the plate marker to the band your going to tune on and the load control fully counter clockwise.

Meter switch to ALC

Flick send switch and peak the drive control, if the needle goes out of the ALC range use the carrier control to back it off until it is at maximum position of the ALC mark

switch meter to IP, then dip the needle using the plate control

switch meter to RF and then using the load control peak the needle

Send switch to rec position

mode switch to cw, either wide or narrow your choice.

flick send switch to send

Very quickly and I mean quickly while watching the watt meter, peak the output using the plate and load control, this should take no more than a few seconds, if your not able to do it in one go due to limited experience flick send switch back to rec for a few minutes.

Repeat this until you get maximum output, if you have low output then try and turn your carrier pot clock wise, you will see the output rise, on all of my 530s and 830s radios my car is set to less that half of the potentiometer's travel and this is subject to band being tuned.

This will take a few attempts but once mastered you will be able to tune within the 5 second timeframe.

The benefit of having an external watt meter is so you can easily see that you have maximum output and have the PA tuned properly thus taking a heap of pressure of you tubes and associated parts in the PA and final board.

Once your happy with output, turn send switch to receive, mode switch to USB\LSB, mic gain to about 10 o'clock position, meter to ALC, speak into mic and see if the meter moves in the ALC. Now if you have ALC movement back the mic gain off (CCW) until the ALC needle just moves, this will ensure you have good clean audio, check the output with whislt talking and

if you want use a whistle unless of course you have a two tone generator.

Subject: [TS-520_820_530_830] RE: RE: RE: YouTube Video of Tuning procedure.

Yes, the question of ALC is the most confusing to me. As you say, there are many of people that do various things to keep the meter within the black ALC range. A new driver tube with CAR set in the middle goes way past the ALC range on the meter. Do I then lower CAR to not go past this range, or you said it doesn't matter, and I just peak with the DRIVE control with CAR at center no matter where the meter goes???? I feel I'm destroying my driver tube and not knowing it because the manual doesn't show you what you should see, or what is optimal when you are doing the ALC step.

My understanding is that it is maximum meter deflection. In other words, you turn the DRIVE control until the needle doesn't go any higher... yes, no?? What you are looking for is the opposite of what you look for when you dip the PLATE?

Sorry, but all this is new to me and I'm learning as I'm going. The manual is not that straight forward and assumes a certain knowledge that was probably very common when this radio was made. Not so common now with all the solid state, turn on and play rigs.

Even K4EAA, has a different tuning procedure than what the manual defines. I cannot find an Elmer in my area that knows about these rigs, at least I haven't found someone yet.

If anyone wants to give me a call and explain some of this in more detail, call me at 559-272-6759. I'm in Pacific Standard Time, and usually up and about until after 11:00PM.

Barry (K0DDR)

---In TS-520_820_530_830@yahoogroups.com, <ts-520_820_530_830@yahoogroups.com> wrote:

There is no SSB loading procedure in any TS830 operating manual that I have seen and no way to load with Mode Switch in LSB or USB unless you inject audio in to the mic jack? Dont know what manual you were reading.

There is Step 4.3 Transmission that clearly describes how to load the TS830 and that is done in CW mode. At Step 9 in clearly states you are now done and fully loaded and ready for CW operation. Need to go on to the CW section to learn how to zero beat but loading is done.

If you had literally followed this Step 4.3 you would not have turned your Car Level Pot back CCW at its conclusion. Where did it direct you to do that?

Only thing they could have added is if you want to run less than 100 watts out you can reduce the Carrier Level pot position to any output power level you desire. Apparently that is not intuitive.

Some points of clarification:

1. Manual says to check resting plate current and set to 60ma. No need to do that every time you load the rig. OK to do, but not required. Once set should not change for a long time. If rig is new to you then should clean the bias voltage adjust pot on rear panel with deoxit and blow out with canned air and adjust for 60ma. You are setting the zero signal operating point (Class AB1).

2. Almost everyone has a question about Step 5 adjusting the Drive control to peak the ALC indication. What ALC peak? Do they mean the printed black rectangular box or the full scale of the panel meter? IT DOES NO MATTER. You are not reading any of the meter scales. You are NOT setting grid current levels. You are adjusting the Transmit Mixer and Transmit Drive tuned circuits for resonance so you will have maximum RF drive (voltage swing) at the control grids of the 6146 finals. Videos will go to great length to show that you must keep ALC indication in the center of the black printed range or at the far right edge of it and to go back and check it after loading and if not to adjust it. All of this is bogus and shows no understanding of what this step is. Some of this comes from long time hams. Just advance the Car Level pot to get a decent indicated level that you can peak. If the level of carrier pegs the meter simply back the Car Pot down a little.

3. After adjusting the Plate Tune cap for a dip in Plate current (Ip) in Tune mode all the KW hybrid manuals have you flip meter to RF Relative Power position to load to maximum relative power output and as a last step go back to Ip meter position to make sure not exceeding maximum plate dissipation. 200ma for the 520/820 rigs and 265ma for the 530/830 rigs. Most 530/830 owners do not load much above 225ma in effort to extend tube life.

No where does KW recommend you load the radio using the plate current Dip and Load method. Old timers do this as they learned it from Class C grid leak bias CW transmitter days. It was only game in town as there were no external wattmeters and they had to watch grid current so they didnt exceed 6146 final tube control grid dissipation and damage the tubes. None of that applies to a KW Hybrid. It is a Class AB1 linear amp. For this reason KW gave you the RF Relative Power meter position to load the radio. In Class AB1 loading to max rf output without exceeding max plate dissipation will result in the max load (best efficiency) occurring slightly to inductive side of true resonance. Hard to see the actual minimum dip in Class AB1 tetrode amps.

4. For all new folks I suggest that since you need a SWR bridge to trim your dipoles do yourself a favor and buy a wattmeter like a Drake W4 or Heath HM-102 and you now have your SWR bridge and a KW hybrid loading aid and test meter. Instead of using the RF meter position leave rig meter in IP and load for maximum RF output power on the external wattmeter (this will be approx 100 watts out or a little less) without exceeding approx 200 to 225 ma. 225ma is a level that Ken K4EAA recommends to ensure long tube life. It is not a hard number.

Using the Wattmeter gives a real power number to look at and simplifies loading and gives instant indication of problems with the rig or your antenna system. These are problems that you as a new person would not likely recognize or understand looking at the Ip meter indication.

Loading one of these radios can be accomplished literally in seconds.

If you pre-set the controls can be done even in CW mode to get that initial plate current dip. Not recommended until you gain some experience.

I have seen no You Tube videos that I would recommend. Most are flawed especially when it comes to peaking the ALC indication and that includes those posted by Extra class holders. Lots of good intentions and little technical understanding of what is happening on the ends of the control knob shafts.

Until you gain some knowledge and experience if you can read, read with comprehension, and observe literal procedure compliance, then the loading procedure steps in all the manuals works just fine.

Tell me about it !
I am a CW operator normally at QRP.

So, I decided to put the Kenwood 830 'on line'.
I went through the whole SSB tuning sequence,
because that is all that was in my manual.
Then at the end they state something like
flip the switch to CW and you are ready to go.
NOT !
The SSB procedures have just canceled out your Carrier,
thus NO CW signal.

I thought I missed something, so I went back through all this several times.

Finally, I just rotated the Carrier Knob and gave myself some Carrier for the CW signal.

All went well after that.

Anyway, Kenwood 830 is a 1985 Cadillac of transceivers.
Glad to have one.
You just have to have more experience than the guy who wrote the manuals.

This is a good Group and the chatter about Kenwood topics is informative.
No magic, but good advice.

Thanks guys.

I'm new to the Kenwood Hybrid. I've been reading quite a bit about them, and one thing in particular I find is there are so many different ways people tune the transceiver. I was wondering if anyone here could recommend a YouTube video that demonstrates the best way to tune the hybrid for transmit. I've found a few YouTube videos. None of them seem to follow the manual when tuning.

Hi Mike,
Thanks for getting back with that helpful info. I was under the impression there was a 530, and 530s,i was wrong,i must have been thinking of a 520 and 520s

Subject: Re: [TS-520_820_530_830] difference between, a 530,and 530s, .

I could be wrong but in the event that Kenny is referring to the 520 verses the 520S then here are some of the differences between those 2 models:

1. The 520S has 160 meters but the 520 does not.

2. The dial on the 520S is different than the 520.

3. RL1 on the GENERATOR Unit in the 520 was removed/replaced with a revised circuit on the 520S GENERATOR Unit.

4. The 520S had the PHONE PATCH IN/OUT sockets on the rear panel but the 520 did not.

5. The 520S has the HET/VFO/CAR sockets plus a 2 pin 13.6VDC socket for the DG-5 digital display but the 520 has none of these

6. The DC to DC converter, DS-1A, was an optional item in the 520S but was standard from the factory in the 520.

7. The 4 position crystal control (FIX) option was located to the right of the meter in the 520 but that switch was moved to an outer ring switch on the LOAD control in the 520S

8. The Meter switch was located on the LOAD control in the 520 but was moved to the right of the meter in the 520S

The TS-520SE is the same transceiver as the TS-520S except for 2 non-supported features:

1. The TS-520SE is designed to operate from 120/240VAC ONLY (the DC-1A DC to DC converter power option is not supported)

2. The HEATER switch was eliminated in the TS-520SE (driver and both final tube filaments were constantly lit as long as either 120VAC or 240VAC (switch selectable) is applied to the TS-520SE and the main power switch is set to ON).

Ok well thanx for the responses everyone but apparently the plugs were not in the right place to begin with. This radio had the 3 pin connector with the clear wire, blank space, then gray (my wire is gray with some black heat shrink near the connector) wire was reversed with the 5 pin white with black stripe etc... before I unplugged the connectors. Now I have I have two pins on the IF board with no connections. Here's what I have now from the RIF pin 1 from radio rear to front. The 3 pin connector clear wire, empty, gray wire. Then the 5 pin connector white with black stripe, gray, red, green, white with gray stripe. Then a 3 pin connector green, purple, gray. then pins 4 and 5 on IF 2 are blank. is this correct now? Id be interested in turning it on again after I get this right.

Dan,

I think you just found out how important it is to take notes/pictures prior to removing any connectors or wires.

With the rig turned bottom up...front panel to your left: the terminal RIF on the IF BOARD is at far RIGHT (or to the rear of the rig), A 3 hole connector with a "clear" wire, middle hole empty, and a "black wire go here...the "clear wire goes to the RIF terminal

The next is a 5 wire connector: colors go from right to left: white...red...green...white w/grey stripe

Hi all

First can I just say I am very impressed with the technical knowledge in this group and people's willingness to help out newbies like myself.

I am trying to take it all in and am about to embark on some light renovation of my 830S so there may be more questions incoming!

In the meantime an easy starter. I have acquired an MC-50 to go with my 830S but it did not come with the lead to connect the base unit to the radio. Does anyone know where I can get a lead from or at least that funny 5 pin plug it uses.

Any suggestions will be gratefully received.

Topic: 45375 Message: 45610

Terry,

I guess the final test you suggested confirms the CW filter is bad. I will pull it out just to confirm.

My signal generator is DDS controlled and is adjustable in 1 Hz steps. I calibrated my Frequency Counter about 3 months ago against a OCXO. According to the counter, my DDS generator is 32 Hz high at 8.830000.

With the generator set to 8.830300 feeding pin 4 on the CAR-2 board, I am able to load the transmitter to full power in CW mode. At this frequency the TS-820S display is reading 14.199.6. Changing the frequency to 8.830400 or 8.830200 cuts the power in half. If I set the generator to 8.830700, I get the 60 ma resting plate current.

After I remove the filter and confirm it is bad, I will order a replacement.
